Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

+ *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.
+ *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.
+ *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.
+ *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.

Über Google Buchsuche

Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter `http://books.google.com` durchsuchen.

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

THE NATURAL HISTORY OF PULMONARY CONSUMPTION.

By A. B. Shepherd, M.A., M.B., F.R.C.P.,
Physician to the Victoria Park Hospital for Diseases of the Chest; Assistant Physician to St. Mary's Hospital; &c.

LECTURE II.—(Concluded.)

I PASS on to that form of phthisis which consists essentially in an extra-alveolar growth—in the fibroid proliferation of the septa of the alveoli. The main symptoms during life are still the symptoms of Morton's definition; but it has a different history in different cases, and its *post mortem* appearances vary, as I believe, with its history. The results *post mortem* are not altogether the same. The alcoholic is not precisely similar to the syphilitic; and both differ largely from that form which, whether in the typefounder, the stoneworker, or the excessive smoker, may be included under the term "anthracosis." Perfectly true it is, though I must say not universally true, that in all these cases there is the opportunity for and the tendency to that one form of dissipation—spirit-drinking—which might bring them all under the one definition of Dr. Sutton's "fibroid phthisis." Even then they would be varieties of one genus, in which the alcoholic poison was modified in a most distinct manner.

I can add nothing, except in the way of illustration, to that "fibroid degeneration of the lungs" which Dr. Sutton has described in the forty-eighth volume of the *Medico-Chirurgical Transactions*. But to this fibroid phthisis belongs, I think, a form very closely resembling that described by him and others, due, as I believe, to syphilis. In common with my friend and former colleague, Dr. Bäumler, now Professor of Materia Medica at Freiburg-in-Breisgau, I had almost taken it for granted as a form already recognised clinically, though up till very lately I had no great reason to search out any authorities on the subject. The pathological change in this form is quite distinct from that—if I may use the term—accidental occurrence of syphilitic deposits in which the lung, in common with other organs, reveals the presence of gummata of varying size and shape and in different stages of development. Clinically these cases agree in the following points: absence of any hereditary history of consumption; distinct history of the syphilitic taint; cough, accompanied by very slight, if any, expectoration; dyspnœa more intense on exertion than the dyspnœa of ordinary phthisis, and more resembling that of emphysema and chronic bronchitis; great emaciation; marked clubbing of the nails; absence of diarrhœa, or any symptoms of intestinal ulceration; absence, too, of any signs of granular kidney. Add to all this that the patients were of well-made bodily structure, and had had good health for some time after the invasion and ordinary results of the syphilitic poison. By those who had not got beyond the idea that "phthisis pulmonaris" is always "tubercular," the decision, as I have had occasion to observe, was easy, though the physical signs were sometimes troublesome and contradictory. There was absence of dulness where dulness, theoretically, ought to have been; sometimes excessive resonance. There was no great alteration of the voice-sounds; there might be creaking at times here and there; there were no *râles* or crepitation (*a*); or in a more marked manner there were signs of induration at the apices, with those of emphysema and bronchitis. And, *post mortem*, the only lung-change found was what is represented in this drawing, which I lay, Sir, before you: the lung almost everywhere indurated; slight dilatation of the bronchi, but not so marked as in the cases of fibroid disease described by Dr. Sutton; almost total disappearance of the alveoli from the fibroid proliferation of their septa; small bladders here and there of emphysema starting up among the hard gristly tissue, and accounting for the signs furnished by percussion and auscultation; small grape-like masses of chalky consistence, the remains of former vesicular pneumonias—or, more correctly, lobular bronchopneumonias—which have long ceased to influence, if they ever influence, the alveolar and bronchial walls; and, as in that case before you, the fresh pneumonia which, depriving the patient of his only

---

(*a*) Sutton, *loc cit.*, p. 30.

breathing surface, gave the last stroke to an organ already hindered in its function. In the best marked form, as in the very case a drawing of which I have placed in your hands, there is nothing like the miliary tubercle, or the grey granulation, or even the yellow infiltration of authors, except it be represented by those obsolescent remnants of former local inflammation: only this fibroid change, which to some writers of to-day represents—and the words lack the true scientific severity—"phthisis with its age forgotten." (*a*)

I would have it distinctly understood that these cases of what I consider to be fibroid syphilitic phthisis are not to be confounded with the common type of phthisis, present by no means unfrequently in persons affected with syphilis, any more than they are to be placed in the same category with such cases as Dr. Wilks has described in the ninth volume of the *Transactions of the Pathological Society* (p. 55), in which fibroid isolated nodules occur. Lancereaux gives a list of various authors who have written on phthisis in combination with syphilis, and proceeds to speak of the form to which I am now referring as interstitial pneumonia. (*b*) He quotes a case reported by Vidal, in which a fibroid change had taken place in the lower lobes; and gives another observed by himself, in which the upper lobe of the left lung showed a radiating cicatrix; the lung tissue fibrous, with numerous yellow points; the bronchi for the most part dilated or contracted, terminating in ampullary *culs-de-sac*. Dittrich, in the *Praeger Vierteljahrschrift* (1850, vol. ii., p. 42), writing on syphilitic affections of the liver, recognises the results of a "syphilitic pneumonia," with the same fibroid production, in a woman aged 27. Dr. Moxon, in the *Guy's Hospital Reports* for 1867, gives, in a "Contribution to the History of Visceral Syphilis," several cases in which this change occurred, *i.e.*, thickening of the fibrous septa of the alveoli. In another paper, published in the Pathological Society's *Transactions* (vol. xxii., p. 40), he records a case which, at any rate so far as the relation of the *post mortem* appearances of the lung go, may be taken almost word for word to apply to that from which the lung drawn here was removed, and to two other cases the records of which, through the death of my friend and colleague Mr. Gascoyen, have been somewhere for the present mislaid. The history of the case I bring before the College is, indeed, only an illustration of the clinical signs I have already drawn. The first symptom was, some few years back, an hæmoptysis. The *post mortem* appearances—to be brief—were those of intense fibroid change, as pictured in that drawing, and visible under the microscope, with numerous bladders of emphysema. Dr. Moxon himself (*c*) notes that the larger bronchial tubes in his last case were unnaturally contracted; and, though I do not wish to push my own observation beyond the fact, so far as I have been able to see at present, the dilatation of the tubes in "fibroid phthisis," or in anthracosis, is not reached in this form, microscopical preparations of which, together with a portion of the lung from which the sections were taken, are exhibited on the table. Dr. Moxon in his earlier paper had answered in the affirmative the question, "Is there a syphilitic form of phthisis different from tubercular phthisis?" (p. 372) but in his last contribution he gives a distinct denial to the proposition I am attempting to support. Dr. Sturges, in his book on the *Natural History and Relations of Pneumonia*, only lately published, gives a case (p. 185) which he considers to be "an instance of fibroid lung, probably the result of syphilis," occuring in a gentleman a little past fifty, easy when at rest, but breathless on slight exertion. "The patient" (I quote Dr. Sturges's words) "was of healthy family, of active business habits, with no tubercular or phthisical history: but some years before he had contracted syphilis. His first notice of illness consisted in an attack of hæmoptysis; and from that time he had complained, and complained only, of impaired breathing power." A woodcut of the appearances found in a case of the same kind, communicated to the author by my friend and colleague Dr. Cheadle, I place, Sir, in your hands, in spite of some misgiving that my former teacher, one of the Censors of the College, may accuse me, in using it as an illustration, of having proved more than I really wish to do. Thanks to the same colleague, I saw only yesterday a man forty-three years old, aged before his time, who bears the marks of a syphilis at least, he says, twenty years ago, whose health has been, so far as he allows it, good up to the commencement of the present winter. For eleven months after contracting the disease he was in the Birmingham Hospital. It is scarcely to be wondered at that he presented no so-called secondary symptoms. Now, he has laryngeal cough and stridor; absolute dulness, without moist sounds, at his right apex: a case at present to be watched (*a*)

Lancereaux had spoken of the few facts on which his notice of this supposed syphilitic lung-change was based. That remark still holds good; for, in the very valuable paper on Syphilis by Professor Bäumler in Ziemssen's *Cyclopædia*, the only cases he quotes—and I can well answes for his industry—are those of Vidal, Dittrich, and Moxon. A doubtful case of the same kind was published by Cornil in the *Gazette Médicale* for 1873 (p. 185); and though, perhaps, it is hardly possible to claim Bayle's twenty-third case as belonging to this class—a case of "tubercular phthisis complicated with melanosis" in a man aged 62, who "had often contracted the venereal disease" (*b*) it is far less possible to pass over Morton's chapter (lib. ii., vii.), "De Phthisie à Lue Venereâ orta." His observation of its clinical symptoms was made with his usual keeness; "Semper enim (quantum ego observavi) est genii Asthmatici, Phlegmate viscoso, et dyspnœâ magis, quàm urgenti tussi stipari solita." (*c*)

With reference to that third form of fibroid change which, called roughly by the Germans "Staubinhalationskrankheit," includes under one name a pathological result due to the inhaling of fine particles of coal, iron, stone grit, tobacco, or cotton, we in London have, perhaps, but small experience. But since Wepfer, (*d*) over a hundred and fifty years ago, noticed its occurrence among millstone-workers at Waldshut on the Rhine, and tried to see for himself its pathological changes, and tried in vain—"quia hactenus nullo cadavere potiri potui, quamvis id precibus et pretio tentarem" (*e*)—experience as to this alteration is becoming large. Without referring further at this moment to a paper written by Dr. Peacock, who begins by quoting Wepfer, in the twenty-fifth volume (p. 214, &c.) of the *Medico-Chirugical Review* for 1860, the literature on this subject, especially of late years in one periodical, the *Deutsches Archiv fur Klin. Med.*, has been multiplied exceedingly. Zenker, Seltmann, and give Riege full bibliographical references in addition to their own experience. I have to thank my colleague Dr. Andrew for allowing me to lay before the College one of the most marked examples of this affection which it has been my fortune to see. The patient was a French millstone-maker, aged 45, who had worked at his trade since his apprenticeship. He had had a winter cough for many years; had never suffered from syphilis; "had an attack of congestion of the lungs five years ago;" had worked hard, and had undergone great domestic trauble. And yet with the lung pictured in this drawing—and, with the exception of cavities and dilated tubes, the whole of both lungs was in that condition—he managed to live till he was killed by a pericarditis. The note made by Dr. Bristowe in reference to one of Dr. Peacock's cases (*f*) has its exact repetition in this

patient's lung. "The diseased portions of lung were much indurated, having generally an opaque whitish hue, but being thickly studded with black pigment. Under the microscope, little or no trace of original lung-structure was visible; but the diseased masses appear to be made up of dense closely arranged fibroid tissue, studded here and there with numerous irregular groups of black pigment." The lung itself, and microscopical sections of it, are here on the table for the examination of those gentlemen who wish to see them when the lecture is over.

Physiological experience points in these cases even more markedly than in other types of phthisis to the part the lymphatics seem to play. I have no need to refer to the calculations, whether as to chemical constitution or to weight, of the foreign particles found in the lung-tissue of these cases. That they do occur in the lung-tissue is a settled fact. By what way they reach it may be still an open question. Knauff, (*a*) writin gin 1867, had sketched to his own satisfaction the following process. In the case of the inhalation of particles of carbon, he held that, while in healthy persons these particles led only to their own expulsion from irritation of the bronchial mucous membrane, in persons continually subjected to their presence, they caused, by repeated and increased catarrh, extensive destruction of the ciliated epithelium, and, by accumulation, further necrotic processes, till a way was opened into the lymphatic vessels. Sikorsky, in 1870, (*b*) showed from his experiments that carmine-particles, injected under the form of carminated ammonia into the lungs of cats and dogs, penetrated between the epithelial cells of the bronchial mucous membrane into the lymphatic system of the bronchi. The further explanation of these facts is furnished by Dr. Klein, (*c*) who has demonstrated the presence of certain interepithelial connective-tissue cells, to which he gives the name pseudostomatous tissue. These occupy a system of spaces which, in the normal state, do not form open communications between the surface and the lymph-canal system, but in certain circumstances, under which they are distended, may be converted into free passages between the two. The same interepithelial cells are found in the interalveolar septa, and may aid absorption from the alveoli themselves. These cells occur in the positions indicated in these diagrams.

It is this form of phthisis—the third of my temporary division—which has been, as we are reminded, "unfortunately called fibroid, in which death often occurred through the indirect result of tubercles that had terminated their career;" (*d*) it is this form which has carried the upholders of a specific tubercle into theories of the most startling kind, till it almost seems as if, in their allegiance to a Circe of their own creating,

"*τοὺς αὐτὴ κάτεθελξεν ἐπεὶ κατὰ φαρμακ' ἔδωκεν.*"—*Odys.*, x. 213.

And yet, in obedience to them, we are to believe that histological growth, or, if you will, pathological hyperplasia from already existing tissue, is not the simple thing it seems to some of us to be; but, against our own eyesight and our common sense, are to accept without questioning this *sacramentum* of "Tubercle." We might as well, it seems to me, on the same grounds give the same name to interstitial keratitis, or to the hyperplasia of irritated cartilage. Virchow, writing on tumours, (*e*) had laid down a rule which, in the case of this fibroid phthisis, it would be well to follow: "Investigations ought not to be conducted with a view to determine whether they have a physiological" (he might have said here a pathological) "type, or whether they have a specific stamp impressed upon them; our final answer depends upon the question whether they rise at a spot to which they belong. "And the change arises in fibroid phthisis at a spot to which it does belong, and as is clearly due to the local irritation as is the cell-growth in irritated cartilage and cornea. Here once more the words of Addison apply: "I fail to discover what I had always been taught to consider as essentially tubercle: a distinct, separate, or rather separable body of a particular colour and consistence, embedded in, and, although adhering to, supplanting a portion of the ordinary tissue of the lung. On the contrary......there is not one of the varied morbid conditions coming under the denomination of tubercle which has not appeared to me to result from changes in or on the natural tissues, rather than from any separate and well-defined deposit displacing these tissues. These morbid changes have appeared to me to be perfectly identical with those of inflammation." (*a*) And Sir—to close with those words which the consulting physicians of two hundred years ago used to append to the written statement of their opinion—"*Ita censeo.*" (*b*)

◆

ON THE ETIOLOGY AND TREATMENT OF SCROFULOUS OPHTHALMIA. (*c*)

By H. CRIPPS LAWRENCE, L.R.C.P. Lond., &c.

SCROFULOUS ophthalmia is a common, frequently a complex and chronic disorder.

So long as a disease continues frequent, undoubtedly greater opportunities arise to study it, but in order to this time, as well as opportunity, is necessary. It is in respect to both of these requirements that general practitioners experience a double disadvantage; in earlier life time is too abundant, for the cases are not forthcoming; and as facilities for frequent observation arise, then are general practitioners unable to devote the time they wish, and which is necessary adequately to study the cases. Again, when a disorder comes under notice which is frequent, complex and chronic, it cheats us by its very subtlety, for the mind is apt, in practice, to regard the frequency and chronicity as being almost unremediable factors, while the energy of treatment becomes concentrated on combating the complications. Yet, perchance, the chapter in disease which deals with the method of diminishing its frequency and chronicity is even of greater value than that which treats of the complications.

Scrofulous ophthalmia is a disease respecting which, as regards its nature and treatment, most members of the profession hold fixed and definite opinions; yet, how numerous and various are these!

In this communication I omit a consideration of the diagnosis, complications, and prognosis of scrofulous ophthalmia, but purpose confining my remarks to the etiology or causation and to the treatment of the affection.

Referring to the nomenclature of diseases issued by the Royal College of Physicians, it is remarkable that scrofulous ophthalmia is classed among the diseases of the conjunctiva, and as a general affection of the eye, but no mention of it occurs in reference to diseases of the cornea.

Throughout professional literature on the subject a wide variation is to be found respecting the nomenclature of the disease, whether we instance the employment of the general term scrofulous ophthalmia, or that of "strumous ophthalmia," employed by Sir Thomas Watson, or "phlyctenular" ophthalmia with Mackenzie. Some authors regard these terms as synonymous; others give to each a distinctive and differential value.

Then, when the actual seat of the affection is considered, some authorities regard the conjunctiva as the *locus morbi*; some the cornea; others, both. Some the conjunctiva as primarily and the cornea as secondarily affected; some the cornea as the primary seat of affection with a secondary conjunctival congestion; others maintain that the cornea

b

is the seat of disease, as Dixon, who considers the term "scrofulous ophthalmia" inappropriate, the disease being regarded by him as a scrofulous keratitis, and not an ophthalmia at all.

Such a variety of opinion is little calculated to advance a knowledge of the disease, nor does it tend to promote rational treatment.

In the following remarks will be comprised (a) a brief review of the chief symptoms (local) of scrofulous ophthalmia as recorded by standard authorities on the subject; (b) a consideration of certain physiological data in connection therewith. (c) A reference to the treatment of the affection.

(a) Sir Thomas Watson refers to strumous ophthalmia as a disease belonging to the conjunctiva, affecting scrofulous or strumous children who have been weaned. In enumerating the symptoms of the disorder, he mentions first, slight redness; secondly, great intolerance of light; thirdly, the formation of little prominences or pustules on the surface of the conjunctiva. He then qualifies this description by stating that the redness is partial, sometimes confined to the palpebral conjunctiva. Then he refers to bundles of vessels running from the angle of the eye towards the cornea, and where they stop, small elevations of the membrance occur, called pustules; the line of junction between the sclerotic and cornea being the most frequent site for the formation of these pustules. Photophobia is regarded as a very prominent symptom, sometimes the only manifest one. In Mr. Dixon's article on "Scrofulous or Strumous Ophthalmia," in Holmes' System of Surgery (1st ed. vol. ii. p. 694) the author commences by stating: "If by 'ophthalmia' we are to understand an inflammatory affection of the *conjunctiva*, the disease I am about to speak of ought not to be termed ophthalmia at all. It is essentially a corneal disease, the conjunctiva being only secondarily affected." He then proceeds to note that the phenomena usually attributed to scrofulous ophthalmia may occur in patients who are not scrofulous, or who exhibit "no visible glandular disease." Referring to the local affection, the author describes it as consisting of either a small whitish elevation (the phlyctenula of Mackenzie) or an ulcer. In either case a long plexus of vessels runs from the corneal margin to the morbid spot. No sequence of symptoms is mentioned, no special location assigned for the phlyctenulæ. Mention is made of the increased flow of tears without increased secretion of mucus from the conjunctiva. After noticing that the photophobia is out of all proportion to the extent of the corneal disease, with regard to pain, Mr. Dixon adds: "In some extreme cases the surgeon is surprised to find merely a small whitish elevation (phlyctenula) or an ulcer the size of a pin's head with the characteristic streak of vessels reaching to it from the edge of an almost clear cornea."

The chapter in Mackenzie's work on "Diseases of the Eye" which he devotes to phlyctenular ophthalmia is headed with several synonyms, among which occurs conjunctivitis phlyctenulosa, but there is none indicative of corneal disease. Mackenzie regards the affection as an eruptive disease affecting the conjunctiva, not as a mucous membrane, but as a continuation of the skin over the eye. Among the symptoms he mentions these in the following sequence: 1. Redness of the conjunctiva, at first slight, and confined to the inside of the lids, sometimes a few scattered vessels course through the conjunctiva towards the cornea, at other times no enlarged vessels are visible, and photophobia is the chief symptom, or fasciculi of vessels converge towards the cornea from either angle of the eye, the redness increasing with the disease and the sclerotic may appear injected; 2. Pain, photophobia, and blepharospasm are referred to.

When we come to the comprehensive and literary description of scrofulous ophthalmia by the late Sir William Lawrence, we find him first pointing out certain characteristics of the scrofulous constitution, dividing scrofulous patients virtually into two classes, viz., the "torpid" and "erethitic," and then he proceeds to note the exciting causes of scrofula, mentioning especially cold with moisture; also insufficient or unwholesome food, and to the latter he attached great importance. Cold and inanition serve to explain why infants at the breast are protected by warmth and suitable nourishment from exhibiting the pernicious ophthalmia, to an outbreak of which they are so prone and susceptible from the time of being weaned until the period of puberty. Sir William Lawrence defines the disease as "an external inflammation of the eye, originally seated in the conjunctiva, often affecting the sclerotic coat and cornea, seldom going deeper, but occasionally extending even to the iris." The symptoms are described in following sequence: 1. Redness of the conjunctiva, partial, slight, and chiefly affecting the palpebral conjunctiva; 2. Fasciculi of vessels run towards the cornea on the surface of the conjunctiva, stopping at the margin of the cornea or extending over its margin; where these fasciculi terminate the phlyctenulæ occur; 3. Blepharospasm, photophobia, and epiphora follow; 4. Constipation and disordered digestion are, especially noted; 5. Morning exacerbations and nocturnal remissions in the course of the disease; 6. The erratic nature of scrofulous ophthalmia is noticed—how it goes and returns rapidly, affects one eye, then the opposite, and alternates with other manifestations of scrofula in the nose and ear.

The late Professor Miller, of Edinburgh, regarded strumous, scrofulous, or phlyctenular ophthalmia as being essentially a disease of the cornea, of which the conjunctival congestion is only symptomatic, occurring in strumous children. The following sequence of symptoms is noted: 1. Photophobia quite out of proportion to any obvious cause; 2. Enlarged vessels collected into fasciculi, stretching from the corneal margin to the phlyctenulæ, or to terminate in an ulcer; 3. Morning exacerbations with nocturnal remissions. The leash of vessels is considered the characteristic sign of the disease. Mackenzie devotes distinct chapters in his work to scrofulous sclerotitis and scrofulous corneitis and iritis respectively, but the symptoms of these he differentiates manifestly from those of phlyctenular conjunctivitis or scrofulous ophthalmia.

Mr. Soelberg Wells describes the symptoms of scrofulous ophthalmia thus:—1. Heat and itching in the eyelids, with a watery and irritable condition of the eye; 2. Photophobia, lachrymation, pain in and around the eye (ciliary neuralgia), the latter being less intense when the phlyctenulæ are confined to the ocular conjunctiva, increasing when the cornea becomes invaded; 3. Conjunctival and subconjunctival injection varying with the amount of the disease. When the injection is partial and confined to a part of the ocular conjunctiva, a fan-like bundle of vessels is noticed extending from the retro-tarsal margin towards the edge of the cornea, the base towards the palpebræ, the apex at the cornea. At the apex of the triangle of vessels one or more herpetic vesicles or pustules appear, semi-transparent or yellowish-white, often occurring symmetrically at the outer side of each eye. These phlyctenulæ soon shed the epithelium covering them, leaving an ulcer which gradually absorbs, or increases in size and depth, when the contents become yellow and opaque. The epithelium may be reformed, and the contents undergo absorption. When the phlyctenulæ appear the irritation lessens, especially when the epithelium is shed and the contents escape. Increase in the number of the phlyctenulæ augments the symptoms. The most frequent site of these phlyctenulæ is at the edge of the cornea, but they often occur simultaneously on the conjunctiva and cornea. Beyond this the pustules may increase in size and depth, the inflammation affecting the subconjunctival tissue causing an episcleritis, and even reaching the superficial layers of the sclerotic.

The above narration at some length of the recorded observations of the authors quoted is an important preliminary, for it is somewhat difficult to realise but for the distinctness of the titles of their papers on the subject, that each writer is describing one and the same disease. The differences of description assume greater importance from the fact that the subsequent treatment recommended varies with each authority. The outcome of this varied teaching may be thus briefly compared:—An inflammation may attack the eyes of scrofulous children from the time of weaning until puberty. According to some authorities the conjunctiva is chiefly implicated, while others maintain the cornea to be the seat of disease. Now one of three positions may be accepted—1. Each class of authorities may observe correctly, and describe under one name two essentially distinct diseases; or, 2. One authority may be correct and the other incorrect in observation; or, 3. One may be correct or incorrect in the description or interpretation of observed facts.

Four of the six authors quoted evidently regard the disease as conjunctival, and two as essentially corneal in nature; and it is remarkable that the four who hold the former opinion all note an injection of the palpebral conjunctiva as an initial symptom; the two others omitting a notice of it. Again, these latter authors omit any notice of a scrofulous conjunctivitis in their works, while both Mackenzie and Mr. Soelberg Wells, who hold the conjunctival view, each devote a chapter to the consideration of phlyctenular corneitis or keratitis scrofulosa. Moreover, the symptoms they associate with scrofulous corneitis, while differing manifestly from the terms in which they themselves depict the features of phlyctenular ophthalmia, do closely resemble the descriptions of phlyctenular ophthalmia given by Mr. Dixon and Professor Miller, who both regard it as a corneal disease. None note whether the palpebral congestion attacks both upper and lower lids, or one before the other.

Photophobia is universally referred to, but the position it holds among the symptoms in point of sequence varies. The fasciculi of vessels are described by those who hold the conjunctival nature of scrofulous ophthalmia as passing towards the phlyctenula, in a direction from the retro-tarsal margin towards the cornea, while the others describe the vessels as running from the margin of the cornea to the phylctenulæ. As regards the phylctenulæ themselves, none mention whether they precede or succeed the appearance of the fasciculus of vessels, nor indeed when the spasm of the orbicularis occurs in point of sequence. Surely the sequence of the symptoms is an important point towards determining the etiology of the disease, and also in reference to the subsequent *rationale* in treatment.

(b) It will be impossible to do more now than glance at a few of the physiological features connected with the symptoms presented in cases of scrofulous ophthalmia.

In reference to photophobia, it is still open to discussion whether the retina be implicated or not; whether there be a hyperæsthesia of the retina *ab initio*, or whether the sensitiveness of the optic nerve be secondarily exalted by irritation of the terminal branches of the corneal nerves, which Klein has traced to the cells of the corneal epithelium, and almost to the surface of it.

Then, again, surely the sequence of photophobia, blepharospasm, and epiphora is important to determine; whether or no, in cases where little or no congestion is present, we are to look for an explanation to the distribution of the lachrymal branch of the ophthalmic division of the fifth nerve, remembering that this lachrymal branch, after passing through the lachrymal canal, goes to supply the conjunctiva, the orbicularis oculi and skin of the upper eyelid. Mackenzie adduced this nerve distribution as an explanation of those cases "where perhaps scarcely an enlarged vessel and as yet no phlyctenulæ have made their appearance."

Dr. Handfield Jones has published some remarks on a case of scrofulous ophthalmia in the *British Medical Journal* of May, 1871, in which he inclines to a view of a nervous hyperæsthesia of the retina, as a state of excitement without power, which may serve to explain the photophobia. This view was entertained by Mirault (*Archives Générales de Médecine*, tome xx. p. 477), who in 1829 regarded the photophobia in scrofulous ophthalmia as being due to an irritable condition of the retina inducing a reflex action of the orbicularis oculi.

Photophobia, epiphora, and blepharospasm ensue if a portion of dust settle on the upper eyelid, for the sensitive fifth pair is thereby excited, whence a reflex action of the portio dura or muscular nerve is induced. The phlyctenulæ may, as irritants, act perhaps in a like manner?

The sequential appearance of the phlyctenulæ appears also likely to prove an important point, and whether they be corneal or conjunctival as to site. Mr. T. Holmes, after describing the nature of the phlyctenulæ, ascribes more pain to the corneal than to the conjunctival ones, in that, they being situated beneath the epithelium, thus, even during their formation, probably press upon, or irritate the sensory nerve filaments of the cornea, which become exposed if the phlyctenulæ ulcerate. The photophobia under these circumstances he attributes to these filaments responding to the stimulus of light by common sensation, or else, because they convey irritation to the ciliary region and cause the reflex movements produced by light, as contraction of the pupil, to be acutely painful.

Passing on to the fasciculi of vessels leading to the phlyctenulæ, the direction of these may perhaps indicate a pathological condition varying with their direction.

The appearance of the leash of vessels also, in point of sequence, is important in relation to the formation of the phlyctenulæ. The development of the herpetic vessels or ulcers is noticed by Mr. Henry Power in a paper on strumous ophthalmia in the *Practitioner* for October, 1872. Therein he quotes the researches of Iwanoff to the effect that the first stage consists in a minute collection of nuclei or nucleate cells, between the epithelium and the anterior layer of the cornea. These appear to be a proliferation of the corpuscles of the sheath of the nerves, or at least to travel along the nerves between the sheath of Schwann and the nerve substance, and thus form a pale vesicular like swelling!

Do these phlyctenulæ result from some morbid process in the sheath of the nerves, and precede the formation of the plexus of vessels of the conjunctiva? In this case the "conjunctiva is to the cornea," as Benjamin Travers has shown, "what the periosteum is to the bone; it nourishes the superficial lamellæ." Or, on the other hand, do the fasciculi of vessels ever precede the formation of the phlyctenulæ? and if so, with what intent?

The questions of constipation and disordered digestion have a reflex value, as excitants, if not to the development, assuredly to the aggravation of scrofulous ophthalmia. All authors insist largely upon the necessity of not overlooking this factor in the chain of symptoms. To these Sir William Lawrence attached great importance, as explaining the photophobia. The author of the article on "Scrofulous Ophthalmia" in Copland's Dictionary of Practical Medicine attributes the photophobia "rather to the state of the organic nervous system." On reference to the distribution of the branches passing from the superior cervical ganglion of the sympathetic two branches may be traced, of importance in relation to this; one will be found distributed to the ganglion of the root of the pneumogastric nerve; the second to the ganglion of the trunk of the pneumogastric.

Metastasis is an important feature in scrofulous ophthalmia. The ganglion of Ribes located on the anterior communicating artery is said to connect the sympathetic nerves of the right and left sides. Again, prolongations of the sympathetic nerve upon the internal carotid artery form plexuses upon the cerebral artertes to the pia mater of the brain; also, upon the ophthalmic arteries, pass to the orbit; a minute plexus even accompanies the arteria centralis retinæ within the eyeball.

Enough has been said to indicate how important are the associations of the sympathetic nerve supply, and the following researches which touch upon the question of trophic nerves appear to me of intrinsic value and interest in relation to scrofulous ophthalmia.

Dr. Rutherford first demonstrated the action of vaso-inhibitory nerves in parts the seat of active nutritive change. The stomach becomes congested during digestion. Division of the vagi at this time causes blanching of the gastric mucous membrane, owing to the influences which pass through the vagi to keep its vessels dilated being cut off. In an article on the effects of trophic nerves on inflammation, in the *British Medical Journal* for May 20th, 1871, this is mentioned, and a *résumé* of the subject given, to which I am indebted for the following information :—

Majendie and Longet proved by experiment that division of the fifth nerve within the skull led to destructive inflammation of the eye and its appendages on the side of section. This result Snellen and Bütner attributed to loss of sensibility in the eye, which could not protect itself against external irritants ; but Samuel, whose researches in relation to trophic nerves have been so extensive, controverted this explanation by an appeal to facial paralysis failing to produce like results. Meissner and Schiff demonstrated that the "nature of the lesion of the fifth nerve determines the amount of injury observed in the eyeball." Division of the outer fibres leads to insensibility, while if only the inner fibres be divided sensibility remains, but destructive inflammation ensues. Upon such evidence a trophic nerve supply for the eyeball is assumed. The nature and mode of action of these trophic nerves is a moot point. Some authorities attribute the above results arising from division of the fifth nerve to vaso-motor disturbance caused by paralysis of branches of the sympathetic which run in the trunk. This is probably true, for division of the fifth nerve posterior to the Gasserian ganglion is less fatal to the eye than section anterior to the ganglion where the sympathetic joins the nerve. Others maintain the presence of purely trophic nerves, distinct from the vaso-motor nerves, but whether, if they exist, they act independently of the latter, is unknown.

The more recent experiments of Dr. Sinitzen, of Moscow, have an especial interest in reference to scrofulous ophthalmia in its relationship with the sympathetic system (*Centralblatt für die Medicinischen Wissenschaften*, No. 11, March, 18, 1871). Evulsion of the superior cervical ganglion of the sympathetic in rabbits rendered the corresponding eye more capable of resisting external irritation, and even completely antagonised the effects of division of the fifth nerve. Dr. Sinitzen extirpated one superior cervical ganglion and then introduced into the corneæ of both eyes at corresponding points glass threads, of the same size, and at the same depth. In the eye of the sound side resulted conjunctivitis, pannus, purulent infiltration of the cornea, and further destructive changes, while the eye on the side operated on exhibited little or no alteration. Again, evulsion of the superior cervical ganglion immediately before or after the operation of division of the fifth nerve within the skull prevented inflammatory results. Moreover, destructive results having commenced after such division, provided the cornea was not opaque, they were arrested entirely, and complete reparation ensued. Upon evulsion of the superior cervical ganglion, when complete reparation was impossible, evulsion of the superior cervical ganglion caused improvement or arrest of destructive inflammation, though no precautions were taken or necessary against external irritants. Dr. Sinitzen attributes these remarkable results to the increased vascularity and temperature of the eye induced by the aforesaid evulsion. He found that irritation of the depressor nerve by causing dilatation of the vessels rendered both eyes equally resistant against inflammation from irritating substances. On the other hand, ligature of the carotid rendered evulsion of the superior cervical ganglion impotent to check the effects of division of the fifth nerve.

Trophic nerves for the eyeball are forcibly suggested by such experiments. The writer of the article which refers to Dr. Sinitzen's researches then adds, that possibly the trunk of the fifth nerve contains afferent fibres ; not sensory, by which the tissues excite an inhibitory action on the vaso-motor centres, and thus produce dilatation of their vessels, and thereby regulate their own vascularity and nutrition.

The recorded observations of standard authors on scrofulous ophthalmia, already quoted by me, manifestly vary : the symptoms present no line of sequence ; and it could be easily shown as an addendum, that the modes of treatment recommended also differ.

Clinical Records.

PRESENTATION OF HAND WITH VERTEX ; DELIVERY BY TRACTION ; POST-PARTUM HÆMORRHAGE ; RECOVERY.

Under the care of R. Hanslip Sers, M.R.C.S.

On June 9th I was unexpectedly summoned by a village midwife to a case of tedious labour. Upon arrival, I found the patient, Mrs. R., a labourer's wife, restless, feeble, and crying out repeatedly with short and unavailing pains. On examination, she was found to be advanced in the second stage of labour, the os fully dilated, the membranes ruptured, the head and the right hand protruding. The position of the head was otherwise normal, only it did not properly fill the hollow of the sacrum ; it was also exceedingly compressible. Mrs. R. had been attended by me previously during premature births, and twelve weeks ago she slipped downstairs, which led to an illness threatening abortion. Finding the soft parts quite dilatable, I easily passed the left hand into the vagina, and by means of the fingers around the neck of the fœtus—at the same time with the free hand pressing firmly upon the abdomen—exerted gentle traction during the pains. In a few minutes she was delivered of a living, though not full-timed, daughter—being her first born alive. In the course of ten minutes the placenta came away naturally. This was followed by immediate and alarming hæmorrhage ; blood poured out in a continuous stream ; the patient instantly tossed about and became delirious. Without delay I passed my hand and forearm into the vagina and uterus, grasped a handful of clots, and with the other hand exerted a counter pressure on the abdominal surface. The arrest of the flooding was instantaneous. After three or four minutes, the uterus contracted firmly, and then I withdrew my hand, and was glad to find no return of the hæmorrhage. I then applied a heavy book covered with a napkin and surrounded with a firm bandage. The child died within twenty-four hours, but the mother recovered without a single bad symptom.

THE MEDICAL HISTORY OF OUR WEST AFRICAN CAMPAIGNS. (a)

It is most fitting that the record of what has been called a doctors' war should be written by one of that medical staff who contributed so essentially to the success of our arms in Ashantee, and Dr. Gore has done good service by placing his clear and unpretending narrative before the public. We can all remember what terrible anticipations of disaster were current at the outset of the campaign of 1873-4, and Dr. Gore's description of the climate of Western Africa shows how deadly it really is to all unacclimatised persons. A very heavy rainfall save for three months in the year, hot dry air by day, succeeded by cold damp winds by night, and an excessively enervating condition of atmosphere at all times, naturally predispose to disease, and under these conditions we can scarcely be surprised that earlier military operations were attended with a serious amount of sickness.

The history of the first detachment of marines sent to the Gold Coast during the rainy season of 1873 was remarkably significant, for out of 110 officers and men, 12 had actually died, and 77 became inefficient within the short space of 58 days. Such being the case, when it was proposed to undertake military operations on a considerable scale, Mr. Cardwell naturally felt some reluctance in employing a European force, and Sir Garnet Wolseley then took upon himself the heavy responsibility of guaranteeing that the troops should not remain in the country for a longer period than two months. "Provided every recognised sanitary precautions were taken," this far-seeing officer believed that English troops might be employed without extraordinary risk; and it is now matter of history that his little army completed their successful work and returned to England in March, having been on the Gold Coast for exactly five days less than the appointed time. Careful study of the medical arrangements shows how well grounded was Sir Garnet's faith in those to whom their superintendence was entrusted, and on no former campaign in which the British army has taken part were difficult sanitary problems more completely solved than by Sir A. Home, Dr. Mackinnon, his successor in office, and by Dr. Gore, to whom this part of professional duty was officially given. The very graphic description supplied by our author of the shocking condition of Cape Coast Castle, with "its beach one vast cesspit," and foul smells and filth and putrefaction tainting the air at every turn, shows us what difficulties were necessarily encountered and eventually surmounted by the judicious application of sound scientific principles. The fact was fully recognised that by good food, warm clothing, and the avoidance of undue fatigue, much disease might be obviated, and we would draw special attention to the detailed sanitary memorandum issued by Dr. Gore for the guidance of the General Commanding, and which is a model of terse and clear statement of important practical details. Minute directions are given for disembarkation, precautions *en route*, and under the head of diet the very proper rule is enforced that every man on first rising in the morning should take four grains of quinine, followed in fifteen minutes by a biscuit and a strong cup of cocoa; and careful instructions are given for the preparation of hot meals at all the principal halting stations. One of the chief novelties of this campaign was the establishment on a very complete scale of hospital ships, the *Victor Emanuel* being fitted up in the most perfect manner for the reception of 140 invalids, and "so excellent were the sanitary arrangements," reports Dr. Gore, "that every patient who was in a condition to improve at all, showed signs of improvement before he had been twenty-four hours on board." The *Simoon*, stationed at St. Vincent, acted as a receiving ship for surplus sick, who were drafted by other steamers from thence to the Cape, and Brazilian packets, which conveyed them to England, thus forming an unbroken communication between the African bush and the hospitals of Haslar and Netley. On the very interesting subjects of dress, food, and stimulants, Dr. Gore expatiates at considerable length, and we presume that the necessity of expanding his book up to certain limits has induced him to introduce a good deal of elementary physiological padding, which might well have been spared. What we desire is the *special* observation of so experienced a medical officer as the author; but in spite of his somewhat diffused style, from each of his chapters we have been able to extract some useful hints and practical suggestions. The great importance of a light kit is emphatically stated; the use of belts, collars, and all such encumbrances of civilisation is shown to be impracticable in Western Africa, and some very sensible remarks on diet can hardly fail to be instructive to all. The great value of soup, and the restorative properties of Liebig's extract are fully shown, and good cooking is proved to be a *sine quâ non* under a tropical sun, where the appetite tends to flag, and where tinned provisions must be largely consumed. In his remarks on alcohol, Dr. Gore follows the lead of the lamented Professor Parkes, and shows the undoubted value of a spirit ration at the close of a long march, to relieve depression and fatigue, alleviate malaise, improve the appetite, and encourage sleep. Although during active exertion experience showed that alcohol was neither required nor well borne given at bed time, or with the evening's meal, its beneficial influences were proved beyond all possibility of dispute.

(a) "The Medical History of our West African Campaigns." By Surgeon-Major Albert A. Gore, M.D., Sanitary Officer on the Staff of the Quarter-Master General's Department during the Ashanti War. London : Bailliere, Tindall, and Cox. 1876. Royal 8vo. Pp. 220.

The special medical lessons to be drawn from the campaign inculcate nothing particularly new, for it was previously known that all Europeans on first landing must almost of necessity pass through an attack of acclimatising fever. This seems in its mildest form to have assumed the character of an intermittent, "where more aggravated, an irregular intermittent, and in its greatest severity a quasi-continued fever, assuming not infrequently many of the characteristics of yellow fever, and the symptoms were frequently severe, with violent head complications, irritability of the stomach, and various internal congestions. It thus happened that the amount of sickness was large, whilst the mortality was insignificent, and several of the more severe cases of illness under treatment either arose from dysentery in an aggravated form, from hepatic abscess, or from inflammation of the lungs. With respect to treatment, Dr. Gore confirms the views currently held as to the most scientific method of holding in check these tropical affections, and devotes several pages to a very scientific consideration of the action and uses of quinine in ague. There does not appear to have been a very fertile field presented during this campaign for the exercise of surgical skill, the bad powder used by the enemy imparting little penetrating power to the slugs employed as projectiles, and the great interest and value to the historian of this the last of our "little wars," is in the perfection with which all sanitary arrangements were made and carried out by an efficient medical staff. Comparing the results of this forethought and business capacity with the confusion which nearly destroyed our army in the Crimea little more than twenty years ago, shows the great progress made by science in these later days, and the improved modes of organisation which are now at our command.

Dr. Gore has given us a most interesting record of a series of stirring events in which he took an active part, and of eleborate precautions for the maintenance of health, which prove how special were his qualifications for the post of sanitary officer, and whatever the ultimate result of this war may be, we are fully justified in asserting that the way in which it was carried out reflected much credit on the responsible authorities both at home and abroad. In conclusion, we must express our admiration of the way the publisher's work has been performed; nothing could be better than the turn-out of Dr. Gore's work.

◆

THE most recent returns from foreign cities show the following rate of mortality: Calcutta 28, Bombay 30, Madras 34; Paris 24; Brussels 26; Amsterdam 24, Rotterdam 21, The Hague 20; Copenhagen 28; Stockholm 29, Christiana 21; Berlin 27, Hamburgh 23, Breslau 43, Munich 36; Vienna 25, Buda-Peth 47; Rome 31, Turin 22; Alexandria 40; Brooklyn 18, Philadelphia 19, and Boston 19.

Vital Statistics.—From the Registrar-General's return we learn that during last week 5,565 births and 3,228 deaths were registered in London, and twenty-two other large towns of the United Kingdom. The mortality from all causes was at the average rate of 21 deaths annually in every 1000 persons living. The annual death-rate was 20 per 1000 in Edinburgh, 22 in London, 22 in Glasgow, and 22 in Dublin. The annual rates of mortality during the same period in the other large towns were—Norwich 18, Hull 23, Leicester 21, Portsmouth 28, Newcastle-upon-Tyne 21, Birmingham 18, Brighton 20, Leeds 26, Wolverhampton 19, Bradford 20, Sheffield 24, Plymouth 14, Bristol 22, Oldham 28, Manchester 26, Salford 28, Nottingham 20, Sunderland 16, and Liverpool 42. The annual death-rate from the seven principal zymotic diseases averaged 2·9 per 1000 in these towns, and ranged from 0·6 and 1·1 in Norwich and Newcastle-upon-Tyne, to 5·0 and 6·8 in Manchester and Salford. The fatality of scarlet fever showed a decline in Portsmouth, but had increased in Sheffield. In Manchester and Salford 21 more fatal cases of small-pox were registered.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 5, 1876.

THE PHYSICAL PSYCHOLOGY OF CRIMINALS.

IN the last part of *The Journal of Psychological Medicine and Mental Pathology*, Dr. Semple has contributed a translation of an address, which Professor Moriz Benedikt recently delivered under the above title in the Vienna Section of the Medical Association in Lower Austria. The subject is certainly one of much importance, especially at a time when so much attention is being devoted to criminal legislation; while the arguments and speculations of the learned Professor are well calculated to awaken curiosity, and to warrant further investigations, however much they may be open to adverse criticism.

Dr. Benedikt opens his address by confessing that his efforts to establish, on the ground of modern evidence, a natural system of morals, have led him to limit the domain of responsibility in comparably more than is the case in positive legislation, and to regard the impulse of criminal natures in the light of natural laws. The object of his paper is to justify his conviction that "an anthropological change," or, in other words, a deficient organisation of the brain lies at the foundation of the criminal propensity of brigands, habitual thieves, relapsing forgers, and other criminals—that the changes in the brains are, in such cases, of a very gross and palpable nature, so as to admit of easy demonstrations in the *post-mortem* room—and, what is more remarkable, that these peculiarities of cerebral organisation may be recognised during life by a careful examination of the criminal's head.

With respect to the cerebral conformation of criminals, Dr. Benedikt bases his observations on the examination of four brains in which various anomalies of form, size, and position were found to exist; the more important of those arising from the fact that the cerebellum was not covered by the occipital lobes, that there were *plis de passage* in several parts of the brain, and that while some parts were more developed, others were less developed than natural. And he thinks that these four examinations establish the probablity that at least in a large proportion of murderers, the brain is in a low grade of development. In fact, he goes so far as to say that they "must suffice to make judges and ministers of justice, as well as legislators, hesitate in coming to a decision; and if sentences of death are necessary, they should be justified on other grounds." The great question, however, was whether this low grade or perversion of cerebral development, admitting it to exist, could be recognised in the skull of the living criminal, as then we should be able to announce during life the probable existence of cerebral abnormities, and of criminal proclivities. With the view of answering this question Dr. Benedikt, in conjunction with his former pupil, Dr. Badik, physician to the Illawa prison, hastened to examine the heads of 365 murderers in that establishment. The result was that both these physicians were struck with the peculiar cranial conformation of a large number of the criminals, especially with the want of prominence of the external occipital protuberance, with the flatness of the occiput, the marked shortening of the occipital part of the sagittal diameter of the skull, and a want of symmetry in the two halves of the skull which far exceeded that which is usually observed. If, in the normal skull, in a straight line from before backwards, the distance is measured from the fossa behind the auditory foramem to the most posterior eminence of the occiput, it will be found to amount to ⅖ and more of the straight line drawn from before backwards, in the middle line between the forehead and the summit of the occiput (the sagittal diameter). Now in the skulls of some criminals examined, this is not the case, inasmuch as the first line reaches ⅓ or ¼ or less of the second. This deviation Dr. Benedikt calls "Brachycephalia occipitalis."

Another "very characteristic" form of the skull, noticed in 56 per cent. of the habitual thieves in Leopoldstadt, is a condition which the author of the paper calls vertex-steepness (Scheitelsteilheit) or rising up from before backwards." While, for example, the highest point of the crown generally stands a little higher (1½ centimetres) than the boundary line between the part of the forehead covered with hair; that which is uncovered and this proportion is altered in habitual thieves, and there are differences amounting to seven centimetres. But not only have the above abnormities been observed in criminals generally, but they are spoken of as varying in character and in frequency according to the class of criminals in which they were noticed. Thus the vertex-steepness just described is said to be peculiar to habitual thieves. The occipital deviations appeared in the highest degree chiefly in robber-murderers, next in murderers from premeditation, and lastly in habitual thieves, whilst in normal persons the highest degree is very rarely found. On the other hand, the lateral symmetry mentioned above existed in a high degree in 37 per cent. of habitual thieves, but in only 26 per cent. of common murderers.

As if to anticipate and to meet the objections which his critics may probably raise against his views, Dr. Benedikt admits the apparent relationship between them and the doctrine of Gall. But he makes the following distinctions: "The fundamental idea of Gall that the psychical functions are localised in the brain is in a certain degree undoubtedly correct, but the chief defect in Gall's theory is that the latter imagined complicated psychical processes to take place in a definite part of the brain. Murder, thieving, forgegy, &c., are complicated psychical functions. There is not only often a defect of intellect which is unable to foresee the consequences of the deed to be perpetrated, but the factors of such acts are composed of motor and sensory impulses also. It is therefore erroneous to assume for murder, for instance, a definite topographical change in the brain, since that crime is the product of different qualitative and quantitative factors. Another fundamental idea of Gall is that the skull is a model of the brain, and although it has been objected that there are in the skull many accidental prominences which have no counterparts in the brain, his fundamental idea is not shaken, inasmuch as "no scientific man may, even if he does not altogether agree with Gall, dispute the doctrine that the construction of the skull is remarkably proportionate to the whole anthropological organisation in brutes and in man." Therefore, the most that the present state of science warrants us in saying is that the anterior part of the brain is the seat of the life of ideas (*Vorstellungsleben*,) the middle part the seat of psychical action in a motor sense, and the most posterior part the seat of sensations and feelings; and that any marked deviations in the general conformation of those parts may be attended by a corresponding amount of deviation in the confirmation of the skull. In conclusion, Dr. Benedekt justly observes that, even if the view taken by him is correct, it does not follow that punishment must be abolished. The true basis of legislation is not the doctrine of responsibility, but the "protection of the existence of normal persons against the ethically degenerate, and the necessary degree of this protection is an essential measure for the severity of the punishment." But it is admitted that the abolition of the punishment of death would necessarily result from the adoption of the doctrine we have been reviewing. "In some of the worst cases," observes the Professor, "future justice will punish more severely by rightly appreciating the views he has advanced. The modern doctrine of judicial punishment is in a false condition, because it constantly sets free criminals whose relapse is certain, allows them to commit fresh crimes, and then, for the first time, deprives them of the liberty to do mischief." Of what importance, then, must it be if the anthropological study of the brain, the skull and the head offers as the prospect of determining, at least in a portion of the cases, with scientific clearness when a relapse is to be expected. Criminal psychology must supply the factors of which, in each special case, or group of cases, crime is composed, and must determine whether imprisonment and education have eradicated, or can eradicate a part of the factors and the predisposing impulses."

Such is a brief summary of the chief facts and observations contained in this suggestive address, and however much opinion may differ as to its merits, we shall all agree in thanking Dr. Semple for bringing it to the notice of English psychologists. The subject is certainly a curious and an interesting one, and we propose to give it consideration in future articles.

◆

Notes on Current Topics.

The Virulent Outbreak of Cholera at Golwood, in India.

It may be that many of our readers pass the articles we are now publishing on some "Recent Cholera Reports," not deeming the subject one of much interest at a time when we are neither threatened with an invasion of this country by cholera, nor are hearing that any remarkable outbreak of the disease has occurred abroad. But scarcely has the last of these articles appeared in our columns, before we have to notice one of the most virulent outbreaks of Asiatic cholera which have ever been recorded. The facts and observations to be found in the reports above mentioned with respect to the transmissibility and prevention of the disease are, we hope, of themselves sufficiently interesting and instructive to attract attention; but if anything was wanting to invest the subject with additional importance, and to impress upon our sanitary authorities the truth of those hygienic principles and laws to which we have recently drawn attention, it was the intelligence of an epidemic which is not only awful in respect of the extraordinary fatality of the disease, but is even at this remote distance calculated to create no little alarm, inasmuch as it is to be feared that the pestilence will not be confined to the village in which it originally broke out.

We have to await the arrival of the Indian mail before we know the particulars of this sad occurrence, but, according to telegraphic information received by the *Times*, the scene of the outbreak was at Golwood, a village situated on the Bombay and Baroda Railway, and containing about 200 inhabitants. The disease seems to be of a most virulent nature. Within twenty-four hours of its first appearance, fifty-seven cases proved fatal. In three days half the inhabitants had perished, while the survivors, panic-stricken, fled to the neighbouring villages. So rapidly fatal were many of the cases, that the ordinary symptoms of cholera were absent, and the patients were almost instantaneously stricken down by the violence of the poison. Another fact mentioned is that the present cause of the epidemic was the inconceivable state of filth in which the people of the village were living. This was very likely the case, and no doubt when we know further particulars of the epidemic, we shall find that this will prove to be a sad but practical illustration of the powerful influence of one of those conditions on which we have elsewhere shown the transmissibility of cholera to depend.

Nor are we surprised to hear that the panic-stricken inhabitants of Golwood fled to the neighbouring villages "only to be refused admission," for however much the contageousness of cholera may be questioned by Pettenkoffer, and other equally eminent authorities, the natives of India have long entertained a contrary belief; and it is by no means an unusual thing for the inhabitants of a district to barricade themselves against an attack of the disease.

Compulsory Superannuation by Process of Law.

The Omagh Board of Guardians have been defeated in a legal process instituted by Dr. A. H. Robinson, lately their medical officer, to compel them to pay his superannuation. It appeared that Dr. Robinson having retired from office, the guardians, after the usual five weeks' notice of motion, voted him a superannuation of £66 a year, but on the same day, a five weeks' notice of motion to rescind the resolution was given by one of a hostile minority. In due course the grant of superannuation was sent up to the L.G.B. for approval, who sent down their sealed order in confirmation of it on the day on which the rescinding motion was to have been made. Nevertheless the guardians reversed their former decision and rescinded the grant. Dr. Robinson waited until the first fall was due, and then sued the guardians. The Chairman of Quarter Sessions decided that the issue of the sealed order completed the transaction, and that any subsequent recision was futile, and gave Dr. Robinson a decree with full costs against the guardians. The case is especially interesting, because it was one of the instances in which a grant of superannuation was resisted because the medical officer happened to be in independent circumstances, although admittedly he was entitled to it on the ground of long service. The fact that the grant was approved by the L.G.B., while a contrary resolution was on the books, may be presumed to indicate their opinion that superannuation ought not to be refused on such grounds.

Conjoint Scheme for Ireland.

We understand that the Board of Trinity College have renewed their action in furtherance of a conjoint scheme of examination for Ireland, having appointed Dr. Apjohn, the Reverend Dr. Haughton, Dr. Stokes, and the Reverend Dr. Carson as a committee to confer with similar committees of the Colleges of Surgeons and Physicians. The Apothecaries Company has not been included in the invitation to co-operate, and as the place of that institution has been taken by the Irish Phamaceutical Society, its place in the scheme which operated against unanimity in the former deliberations will not need to be discussed. The English conjoint scheme has been again revised, and will be at once submitted to discussion, and progresses, we may hope, towards final settlement.

The University of Durham.

We hear that at a meeting of the authorities of the University of Durham, holden last week, it was resolved to admit qualified practitioners to examination for the M.D. degree, as at St. Andrew's University, without residence. Durham has hitherto done so little in the way of medical education, and those who went up for the M.D. were so few, that at last year's meeting of the General Medical Council more than one member expressed the view that it had but little *raison d'être*. We trust this action of the authorities will produce satisfactory results; there are many in the profession quite capable of passing a university examination, but whose time is too valuable to go into residence for four years.

Chisel or Saw for Osteotomy.

It has been suggested that in subcutaneous osteotomy, the chisel will splinter the bone and lead to necrosis, and that the saw makes *dust* which is a possible source of suppuration. In the London Hospital, a case presented itself at which it was necessary to remove the upper end of the femur, and Mr. Maunder took the opportunity of demonstrating the precise effect of his chisel on the living bone. The instrument cut the bone without splintering it.

New Preparations.—Preparations of Terebene.

The active disinfecting and deodorous properties of terebene have been utilised by Messrs. F. C. Cleaver and Sons, Perfumers, and Fancy Soap Manufacturers, in a variety of useful and elegant preparations for the toilet, such as terebene soap, tooth powder, shaving cream, jelly for chapped hands, &c., &c.

Terebene is an oleo-resin which, when exposed to the air, emits an odour of a flagrant and agreeable character resembling the scent of a pine wood. It is both antiseptic and deodorant, and if a gentle heat be applied to a vessel containing the liquid, an agreeable and healthful fragrance may be diffused through a sick room. The preparations referred to all contain a large percentage of terebene, and are therefore a very great improvement in a scientific and sanitary point of view over the ordinary scented soaps and toilet preparations now so largely in use among the ladies of all nations.

Syrupus Cinchonæ Alcoholicus.

The alcoholic syrup of bark is an elegant preparation introduced by Messrs. Schacht and Towerzey. One drachm of the syrup is calculated to contain the medicinal properties of twenty grains of the finest Peruvian bark, an alcoholic extract being made, and then combined in the form of a syrup.

Half a teaspoonful of the syrup mixed with two tablespoonfuls of water produces a translucent mucilaginous and pleasantly bitter stomachic draught.

The London University and Vivisection.

At the meeting of the Senate of the London University last week, Sir William Gull moved: "That the Senate do memorialise the Government on the Bill now before Parliament, entitled 'An Act to prevent Cruel Experiments on Animals,' and do pray that the provisions of the Bill be so modified as to meet the objections stated in the Memorial of the Medical Council adopted June 1st, 1876." This was carried by fourteen of the most intelligent members of the Senate against four dissentients. Sir William Gull has since addressed a letter to a morning contemporary, in which he says:—

"Considering the constitution of the Medical Council, composed as it is of representatives of the medical profession from the three divisions of the kingdom, and considering the constitution of the Senate on the above occasion, it is hardly too much to say that no stronger force of enlightened opinion could have been brought against the objectionable clauses in Lord Carnarvon's Bill. Some of the objections have been removed in the Committee of the Lords, but not all. There still remains one of the most important.

"The Memorial of the Medical Council urges upon the attention of Parliament, and the Senate of the University of London by their vote repeat, that the limitation of all experiments to registered places would tend seriously to obstruct genuine scientific inquiry. Private researches which in competent hands might prove of the highest value to mankind, would, by the system of personal licence and certificate, be restricted to individuals of assured character and attainments, and ought to satisfy all the requirements of the case. But as the clause now stands, no one, however high his attainments, or however assured his character, could perform any scientific experiment on an animal, whether under chloroform or not, except in a registered place. Neither could he perform it, as the Bill now stands, without subjecting himself to 'the demands of the Secretary of State to supply him with the result of any such experiment or experiments, in such form and with such details as the Secretary of State may require.'

"Now, when we consider the difficulties of scientific pursuits in general, and of biological science specially, it will be obvious to anyone who has any knowledge of the subject that, as stated in the Memorial, these impediments will obstruct, if not altogether impede, genuine scientific inquiry. When the matter was under discussion in the Medical Council, Professor Lister gave an example how such a measure would operate. Thus it occurred on an occasion to Professor Lister during his autumn holiday to try the effect of a particular form of ligature on an artery. To obtain the ligature for trial was easy, and to purchase a calf for the operation was easy, and to watch the effect while on his holiday was easy and practicable, and it was done with valuable results to surgery. But, as Professor Lister remarked, if it had been necessary (as it will be legally necessary if Lord Carnarvon's Bill passes) to obtain a special certificate for such an experiment, and, further, to obtain a specially registered place in which it must be performed, is it likely that the experiment would have been performed at all? Certainly not. The opponents of science would probably exclaim, 'So much the better.' But are they aware how much they are hindering that knowledge which would serve some wretched sufferer from accident or disease? Illustrations of this kind could be multiplied without limit; at least, the limit is only that drawn by our ignorance and unreadiness to learn.

"When we realise how rare and fleeting are the finer suggestions of the intellect, and how apt to pass by without bearing fruit, unless favoured by opportunity, we may well view with anxiety the prohibitions, which our Legislature are occupied in framing, to the pursuit of science.

"It is to be hoped that the united remonstrances of the General Medical Council and of the Senate of the University of London may still have some force in the House of Commons to set free the hands of the pioneers of knowledge.

"Every member of Parliament has been supplied with a copy of the Memorial of the General Medical Council, now endorsed by the Senate of the University of London; and, whatever may be the final issue of legislation on the matter, whether to pass a 'penal enactment,' to use the words of Lord Carnarvon,—as if the pursuit of biological science was nefarious,—or whether an enlightened and generous sentiment shall meet the objections which are set forth in the Memorial, the medical profession may feel assured that coming time will justify its exertions in the cause of truth."

Now that the Senate of the London University has joined in the protest against this most obnoxious Bill, we look to Mr. Lowe, Sir John Lubbock, and other Members who really understand the importance of the question, to exert themselves with the House to obtain further amendments, or by the machinery which Irish Members seem to know how to employ, to put an end to this monument of weakness and folly on the part of a Government who, it was believed, entertained a higher appreciation of scientific labour than their predecessors in office. Indeed, in a correspondence which has lately taken place with the Royal Society on the endowment of research, it is broadly asserted that, being "fully aware of the great difficulties which surround the question of the direct encouragement of research, and of the labour and responsibility that must necessarily be entailed on those who undertake to organise experiments in this country, they gladly knd they may reckon on the cordial co-operation of the Royal Society, to whom they naturally first appealed to aid them in this matter." Can this be intended, or do they mean to throw dust in the eyes of those whom they are about to brand as "ticket-of-leave men," and place at the mercy of the common informer? The interests of our profession more than ever demand an increase of political influence.

Medical Microscopical Society's Conversazione.

THE President and Committee of the Medical Microscopical Society had a very successful gathering of members and their friends on Friday evening last. The display of specimens was of a varied and instructive character. The centre table was devoted to a tolerably complete set of specimens illustrative of Green's Pathological and Morbid Anatomy. A few living specimens were exhibited, as the mange-parasite, removed a few hours before the meeting from a dog. This, in spite of the heat of the room, remained in a very active state a greater part of the evening. In instruments, Mr. Giles's apparatus for micro-photography occupied a conspicuous place: a portable and compact student's microscope, after Hartnack's model, by Pillischer, demands commendation; also a portable instrument by Browning. The body of this microscope, by a novel arrangement, turns upon a joint and packs up parallel with the length of its stand. It possesses other advantages which we may briefly mention. The instrument is perfectly balanced in any position, the weight being so evenly disposed over the axis that it does not require any clamping arrangement.

The instrument is well adapted for use as an aquarium microscope for viewing objects in tanks, flowers, seeds, or minerals. This is effected by the aid of a special adapter with a second focussing adjustment, which is supplied for the purpose. The great length of the rack motion enables the instrument to be used with a 4-inch objective. A fine adjustment is in a convenient position on one side of the instrument, for use with the right hand of the observer. It works without lateral motion or perceptible loss of time. There are compensating adjustments for wear to all the superficial motions. When in use it is as steady as a stand of the ordinary kind.

Leaders in Medicine and Surgery.

THOSE of our readers who attended the recent brilliant *conversazione* of the Obstetrical Society of London, held at the Royal College of Physicians, will remember anxious throngs around a large carbon photograph picking out and criticising the faces of friends and prominent members of the profession in the group of 183 which Messrs. Barraud and Jerrard had reproduced in the picture-before them. That plate, measuring about 30 inches by 20, is now published by the artists at their studio, and is a fair representation of "The Leaders in Medicine and Surgery" at the present time.

We, however, fail to understand why Mr. Stone, the Bedell at the College of Surgeons, is introduced as one of the "leaders in medicine and surgery," inasmuch as he is not a member of the profession, and the background of the picture represents the interior of St. Bartholomew's Hospital, not the College of Surgeons. Of the remaining 182 figures all are medical men, and some very striking likenesses meet one at first sight. The three in the foreground are Sir James Paget, Sir Thomas Watson, and Dr. Risdon Bennett, President of the College of Physicians. Her Majesty's Government will perhaps graciously complete the trio by making the latter a baronet beside his illustrious *confrères*. Immediately behind are Sir Wm. Jenner, Sir James Alderson, Mr. S. Lane, &c. The face of the oldest "leader in medicine," Dr. Billing, is seen prominently on the right smiling encouragingly on his juniors with that benignity and good humour which eighty-five summers have not effaced. By his side is an excellent portrait of Sir Wm. Gull, full of that characteristic determination with which a casual student of physiognomy would not fail to be impressed. In front of him Dr. A. Swaine Taylor is seen in the striking position of "attention," best understood in military circles. A little behind is Sir Wm. Fergusson, apparently striving to look over the head of Sir Hy. Thompson, of which fact Mr. Christopher Heath, on the other side, is unconscious. Of the other representatives the best portraits are Drs. Arthur and F. J. Farre, Drs. Acland, Pollock, Pitman, Cholmeley, Habershon, Druitt, Graily Hewitt, Stokes, Priestley, Beale, Pavy, Quain, Sharpey, Rolleston, Parkes, Paget (Cambridge), Wilks, Handfield Jones, Bowman, Dobell, Sturges, Bastian, Clark, &c., Sir George Burrows, Sir J. Fayrer; Messrs. Callender, Barwell, Jabez Hogg, Ernest Hart, Spencer Wells, Gant, Barnard Holt, Erasmus Wilson, Quain, Hulke, John Wood, Hawkins, Haynes Walton, Critchett, Carter, &c. Of course the great majority are London men; Scotland is not represented at all; Ireland only by two, Sir D. Corrigan and Dr. Stokes; and the provinces by about a dozen: the difficulty of getting others engaged in large practice from all parts of the United Kingdom will readily explain this apparent deficiency, for which the artists are in no way responsible. From an artistic point of view the picture is excellent, and excepting perhaps Sir William Fergusson and Dr. Taylor, there is an absence of that stiffness which usually characterises large groups of figures. We can readily believe that many will be glad to possess themselves of a copy of "The Leaders in Medicine and Surgery" as represented in the picture before us.

Conversazione at the Royal College of Surgeons, England.

THE *conversazione* at the College of Surgeons on Tuesday last, given by Sir James and Lady Paget, was in every way a most brilliant and successful affair. The President and Lady Paget remained for three hours at their post receiving their guests. The Hall was most attractively decorated with choice shrubs and flowers, and a crowd of ladies, presenting an unusually gay appearance. The library and ante-rooms were rendered attractive by the exhibition of works of art; and at the top of the principal staircase an excellent band of music was stationed, which relieved the buzz and stir of the scene below. In short, nothing was wanting to make the occasion one that will long dwell in the memories of the fifteen hundred who had the honour of an invitation.

The University of Dublin.

THE authorities of the University of Dublin have done themselves no less honour than they have conferred on Dr. Emerson Reynolds, their Professor of Chemistry, and Mr. Howard Grubb, of optical celebrity, in granting to the former their M.D., and to the latter their Mastership in Engineering, *honoris causa*. The proclivities of University Boards are naturally expected to be strongly in favour of men who have won their laurels by life-long labour, crowned in their old age by distinction in their own speciality, and they cannot be supposed to have much respect for youthful aspirants, no matter how distinguished. The University of Dublin has shown that it can recognise scientific attainments and pre-eminent talent without any regard to the age of him who possesses these qualifications, and the high character of Dr. Reynolds and Mr. Grubb fully justifies the unusual distinction which has been given to them.

Dr. Reynolds has been a physician and surgeon since 1865. He entered the profession with all credit to himself, but with exceptionally few advantages or chances of advancement. He is the author of the following works:—"Lectures on Experimental Chemistry," "Mineralogical Tables—a compendium of Chemical Mineralogy," "Chemical Tables for Junior Students," and of the chapters on Sanitary Chemistry in the "Manual of Public Health for Ireland." He has contributed more than fifty papers to the various scientific societies and journals, and has discovered some sixteen new chemical substances. One of these discoveries was that of the sulphur analogue of ordinary urea—the sulphur urea—a body which had long been sought for in vain by chemists. This discovery was fruitful in results, as Dr. Reynolds' investigation was at once accepted, and made the foundation for some thirty-five researches by Continental chemists, in the course of which a number of new bodies have been obtained.

Dr. Reynolds has also worked much at "Spectrum Analysis," and has described a number of new spectra He has very recently succeeded in making a determination of the hitherto unknown specific heat, and atomic weight of the rare element glucinum, and at the same time has devised a method for the direct determination of the atomic heats of the metallic elements. Before the appointment of Dr. Reynolds to the senior, and now the most valuable chair of chemistry in Ireland, that in the University of Dublin, he held the Professorship of Chemistry in the Royal College of Surgeons, the Professorship of Analytical Chemistry and Keepership of the Minerals in the Royal Dublin Society, and the Examinership in Medical Jurisprudence in the Queen's University. He also acted as scientific referee to the Government in medico-legal cases occurring in Ireland.

but has given up the practice, owing to the interference of Assize work with College duties. When we say that he is a worthy, and, for his years, not less distinguished occupant of the chair held by Apjohn, we need hardly add that we approve the selection made by the Board.

Mr. Grubb may be said to have made a character for Ireland as a seat of the manufacture of the highest class of optical instruments. To photographers the "Grubb Aplanatic" lens is a household word, and the high capability of the firm to which Mr. Grubb belongs has been noted by Continental and colonial astronomers, who have entrusted to him the manufacture of the largest sized equatorials and other instruments which only the very highest class of workmen can undertake.

Inoculability of Typhoid or Enteric Fever.

A QUESTION of some moment with regard to the disease which has been designated "typhoid" in pigs, has been settled in so far as enteric fever in man is concerned, so that the time has arrived for us to allude to the subject. Without discussing at this moment whether the pig really suffers from enteric fever, it is certain that this animal is liable to a disease which, with reference to the intestinal lesions only, bears a very superficial resemblance to that malady. But so far as our researches extend, this affection is *not* inoculable, nor has it been transmitted as yet by cohabitation; though another disorder of pigs, accompanied by a cutaneous eruption, is transmissible both by inoculation and cohabitation. We may have reason hereafter to modify these opinions, through further researches; at present we believe them to be correct.

The Veterinary Journal for July gives it as an established fact that human enteric fever cannot be transmitted to man nor to animals by inoculation, nor yet by ingestion (in animals) of typhoid alvine *dejecta*. With regard to the latter, we find from the Reports of the Medical Officer of the Privy Council, published last year, that Dr. Klein has administered them to monkeys, dogs, cats, guinea-pigs, rabbits, and white mice, under the most favourable circumstances, but without producing the slightest result.

For three years, says a recent number of the *Centralblatt*, Dr. Motschutkoffsky, Director of the Odessa City Hospital, has been experimenting with reference to the inoculability of typhus fever; being prompted thereto by the fact that enteric typhus and relapsing fevers rapidly become at times severe epidemics. He was further instigated to this research by the success of Dr. Münch, who succeeded in developing in himself relapsing fever by auto-inoculation with the blood of a patient suffering from that disease. The experiments were made upon men (volunteers), and such animals as monkeys, rabbits, dogs, and cats. The result of his attempt established the fact that inoculation of man or beast always failed to produce typhus and enteric fever; while relapsing fever could be readily induced by inoculation in man, though absolutely impossible in animals. In this disease, in which we have the peculiar filamentous bodies termed *spirilla*, the inoculable matter was the blood, and this appears only to be potent at the onset of the fever or during relapse; if obtained during the period of apyrexia it gave negative results.

The Army Medical Department.

THE *Army and Navy Gazette* states that among the medical appointments which now require to be filled in consequence of the changes effected by the recent Royal Warrant, are the charge of the Sanitary Branch in Whitehall Yard, vacated by Surgeon-General Rutherford, M.D., C.B.; and the charges at Portsmouth, vacated by Surgeon-General Mouat, V.C., C.B.; at Gibraltar, vacated by Surgeon-General Balfour, M.D.; at Netley, vacated by Surgeon-General Prendergast; at Bombay, vacated by Surgeon-General Inglis, M.D., C.B.; at the Cape of Good Hope, vacated by Deputy Surgeon-General Heffer-man, M.B.; and at Manchester, vacated by Deputy Surgeon-General Ewing. In addition to these, the retirement of Surgeons-General M'Illree and Currie, and the death of Deputy Surgeon-General Lloyd (who by-the-bye, was on the point of being relieved) have left Dublin, Aldershot, and Halifax, N.S., vacant. As to future arrangements, all is uncertainty.

Visit of the British Association to Glasgow.

THE arrangements are being actively carried out for the accommodation of the Association in Glasgow, where it will meet in the first week in September. The total sum subscribed to the guarantee fund is now £7,000. The Museum Committee consists of the three divisions—geology, botany, and archæology. The exhibitions will be large and complete, and arrangements have been made for keeping them open, if desired, for some time after the meeting of the Association. The Local Industries Committee has three sub-committees on machinery, chemicals, and textile fabrics, and the materials for a highly-instructive exhibition are being collected.

A number of distinguished visitors have been invited to the meetings, and have accepted the invitations. Amongst others there are the President designate, Professor Andrews (of Belfast), who is to be the guest of Sir William Thomson; the present president, Sir John Hawkshaw, who, with Lieutenant Cameron, the African explorer, will be the guests of the Lord Provost; the Duke of Argyll, one of the vice-presidents (who is to be accompanied by the Duchess of Argyll), will be the guest of Professor Blackburn. Other distinguished visitors have been invited by their friends to Glasgow.

It has been further arranged by the committee that excursions will take place on Saturday, the 9th, and Thursday, the 14th of September, to Arran, Lochlomond, Lochfyne, Holy Loch, Coatbridge, and Paisley, and other excursions are about to be arranged. Mr. Stewart has placed his yacht at the disposal of the Association for a dredging expedition, and Mr. Duncan, of Benmore, has done the same with his yacht, which is specially fitted for dredging purposes. Arrangements have been made with all the leading railway companies in England and Scotland to offer facilities to strangers in coming to Glasgow, as also in any tours they may make before leaving the city. A guide and handbook is being prepared. The meetings begin on the 6th of September.

Medical Bequests.

MADAME HAGEL, of Bordeaux, has bequeathed the sum of 400,000*l*. for the purpose of erecting, near Paris, an hospital for infirm and incurable persons. Such bequests are rare in France, where the expense of erecting and supporting hospitals falls almost exclusively on the State.

Attempted Suicide by Chloral.

Last week a patient was admitted to Steevens' Hospital in a state of coma, produced by a dose of 120 grains of chloral hydrate, which he had swallowed an hour before admission. His mind had for some time previously been bordering on insanity, induced by drunken habits. Shampooing, electricity, and the other usual stimuli aroused the patient at the end of five hours, and he made a good recovery.

Conversazione at the Royal College of Physicians, London.

On Wednesday evening last the President and Fellows gave their annual *conversazione* at the College, the supply of scientific and other objects of interest being quite up to the standard of former years. The Bastic Glass, in various shapes and patterns, and Helmholtz's apparatus for illustrating the transmission of sound were amongst the new things which attracted most attention. The attendance was not quite up to the last year or two, which is probably attributable to the fact that the College of Surgeons gave a similar entertainment on the previous evening. Few, however, of scientific celebrity were absent, and Dr. Risdon Bennett, the recently elected President, may be congratulated upon the success of his first official reception.

Up to the time of going to press, £25,000 had been received at the Mansion House towards the Metropolitan Hospital Sunday Fund.

Dr. Brown-Sequard will deliver (by permission) three lectures on Paralysis as an Effect of Brain Disease, on July 17, 19, and 21, at the Royal College of Physicians, London.

We are gratified to learn before going to press that the marked improvement in Sir William Fergusson's condition continues, and it is hoped that he will be able to go to Scotland for change of air before long.

At the United Hospital Sports in London on Saturday last, five of the events were won by St. George's Hospital students, three by Guy's, and one each by the St. Mary's and University College representatives. Sir William Gull, Bart., presided, Lady Gull presenting the prizes at the conclusion of the competition.

By a curious coincidence the death-rate last week in the three principal cities of the United Kingdom, exclusive of London, was exactly the same—Dublin 22 per 1,000, Edinburgh 22, and Glasgow 22. The rate was unusually low, London, as usual, being lower still, viz., 20 per 1,000.

Since the beginning of the year 361 deaths from small-pox have occurred in Manchester and Salford, including the cases in the Monsall Hospital outside the city. This mortality is probably greater than that of the rest of the kingdom for the same disease.

For some years past St. Bartholomew has been the only hospital in London at which no introductory lecture was delivered at the opening of the winter session. This year, at least, one other—Guy's—will follow the same practice and dispense with the introductory, and it is not improbable that others of the London and Dublin Schools will join in the movement.

Vivisection, like vaccination, does not find quite a unanimous vote from the profession, as was shown in the House of Lords on Friday last, when Lord Cottesloe presented a petition from physicians, surgeons, clergy, and others in favour of a law to put down *entirely* the practice of vivisection. The number of physicians and surgeons who signed the petition was not stated, so that we are unable to guage the extent of opposition in our ranks.

In the Dublin Rolls Court last week there was before his Honour the will of the late William Hogan, of Great Britain Street, who died in February, 1874, possessed of real and personal property to a considerable amount. The suit was instituted by the executors to administer the trusts of the will. The testator, after bequeathing various legacies, directed his executors to distribute the residue of his property after realisation "to such charitable institutions or hospitals" as they might think most deserving of assistance. The residue was over £10,000, but several claims having been made against the estate, the executors, though believing some of them to be groundless, arranged for the present to retain £4,000 stock to meet claims should they be enforced, and agreed on the distribution of £6,300. Amongst other bequests were the following: St. Michael's Hospital, Kingstown, £500; Rotundo Lying-in Hospital, £300; Children's Infirmary, Buckingham-street, £300; Jervis Street Hospital, £300; Simpson's Hospital, £100; Cork Street Fever Hospital, £100; Male Misericordiæ Hospital, £200; Hospital for Incurables, £100; Meath Hospital, £100; St. Vincent's Hospital, Stephen's Green, £100; Mercer's Hospital, £100.

◆

HARVEIAN ORATION.

The late Dr. Parkes was appointed to deliver the Harveian Oration before the College of Physicians. Among his papers was found, after his death, the manuscript of his oration, unfinished, but sufficiently advanced for delivery, and it was read to the College on 26th June by Sir William Jenner at the request of the late President of the College. The following is an abstract of the oration :—

"On the statue of William Harvey, which was erected by his contemporaries of the College of Physicians, and which was burnt in the great Fire of London, was an inscription—'*viro monumentis suis immortali.*' In these days when discovery succeeds discovery so fast that it taxes the memory to remember the discoveries—much more the names of the discoverers—it may be asked, 'Can we call any memory or any works immortal?' Some few names in literature, some few in philosophy, and some among those who have founded or destroyed empires, have echoed down the stream of time for a thousand, or it may be two or three thousand, years, and have thus secured what we call immortality. But will William Harvey be admitted into this scanty band? The answer, I believe, must be that the explanation of the actions of the heart and of the circulation of the blood is not only one of those cardinal discoveries which lie at the very foundation of physiology and medicine, but is from its very nature one of those great landmarks which must remain in the sight of all. When any one examines into this discovery of Harvey's, and gradually recognises its extraordinary importance (for the full sense of what it is grows upon him as he studies it), he cannot but be seized with an urgent wish to know how the mind which solved so great a problem was constituted; how it worked, and how it reached, not merely the probability, but the certainty of a grand natural law. The proof of the circulation of the blood was a discovery in the truest sense of the word—there was no accident about it; no help from what we call chance. It was worked out and thought out point after point until all was clear as sunshine in midsummer. He appears to me to have had in a marked degree what is sometimes called the scientific mind. Harvey was one of those men who are urged on to submit everything to experiment and observation. Some minds possess this power and intenseness of observation in quite an extraordinary degree, so that it really does separate them from other men. A parallel case may be found in music. Men possessed of this power seem to be unable to avoid exercising it. They must observe, must try experiments, must, to use Bacon's phrase, be always asking questions of Nature. In the Middle Ages to put a man to the question was to torture him into an avowal of the truth, and in this sense Harvey may literally be said to have tortured Nature. He was a thorough vivisectionist, and animals of all kinds ministered to his insatiable curiosity. He owns to having used a 'variety of animals,' whose living breasts and pericardia he opened, and if he had lived in these days he would perhaps have met with scant mercy from a Royal Commisson of Anti-Vivisectionists. And yet without that would the circulation of the blood have been discovered? A usual peculiarity of this class of mind is the great ingenuity and imagination men show in arranging their experiments and devising new ones. Every one must have admired the ingenious mechanism by which physical hypotheses are tested and proved. There is not much trace of this in Harvey's works, for the subjects, perhaps, hardly admitted it. There are some parts in his writings which prove he could have shown ingenuity had it been wanted. Yet, on the whole, I should say he was not an imaginative man. He bent his mind on the thing before him. He possessed, however, in a very marked extent one character of the class of minds to which he belonged. He had faith in facts. Now this may seem a common matter, but it is not altogether so. Many observers have a great distrust of the facts they have themselves discovered. They are biased by previous theories; they do not see how their new facts fit in; they think there is some mistake, or they do not really fully see what they have seen. At any rate, they explain away what seems to them strange and unlikely, and really modify or alter what they have found. They are, in fact, honestly untruthful. Harvey was quite otherwise; when he had seen and touched, so to speak, a fact, and knew it was so, he accepted it, no matter how it struck no previous knowledge. To this clear truthfulness he owed his great discovery. In consequence of this faith in facts he overlooks none—he passes by none. Now a common error is to think some facts more important than others; but all are important, and if one is left out a whole heap may fall asunder. Now Harvey omits nothing; he commences with the most obvious and proceeds step by step, nothing is blurred, nothing is left ill defined. His work was composed before the "Novum Organum' was published, but it has been well said by Willis that it might have been planned on the model of that system. The marvellous clearness of Harvey's treatise on the action of the heart and circulation is quite unsurpassed. It is said that not one of his hearers at this College ever doubted his doctrine; and we can well imagine this, when we see the way in which the facts are laid in order—first, this, then that, then a third, and so the mind is led from step to step until the whole is seen clear as daylight. And now, I think, if my conception of the mind is a true one, we can see clearly how the discovery was made. He desired, to use his own words, 'to contemplate the motion of the heart and arteries, not only in man, but in all animals that have hearts, and further by frequent appeals to vivisection and constant ocular inspection to investigate and endeavour to find out the truth.' At first he tells us that all was obscure, and he found the task was so difficult that he was tempted to think with Fracasto 'that the motion of the heart was only to be comprehended by God.' At length all was clear about the heart, and he had, in addition, carefully determined the total quantity of blood in the body of animals. He had also found out the action of the cardiac valves, and was acquainted with the valves in the veins. He seems to have kept the whole facts before him, just as Newton tells us he did with his great discoveries, until light began to dawn. But there were, perhaps, two causes which held him back. We must remember that there were no microscopes to demonstrate the channel of communication between arteries and veins, and, of course, he had no true conception of the immense capillary system. Then, even with a mind of such a class, it is impossible to put aside the influence of previous teaching. The power of the general opinion must impress every man and lead him to see difficulties which are perhaps unreal. At last his great discovery was made. To most of us, I think, if the movement of the blood in a circle from arteries to veins had occurred, the conclusion would at once be that it so completely accorded with all the facts that it must be so. We should be tempted to call out 'Eureka,' like the sage of old. But Harvey's first thought was simply how completely to test and thoroughly prove this idea. In fact, he put his own hypothesis into the assay, and proved its truth so clearly, and by such able arguments, that even at the present day any one wanting to prove the circulation of the blood (microscopic observations and fine injections not being used) must adopt Harvey's method. In fine, he brought his doctrine to demonstration, and proved it once for all; and throughout everything was done by observation and induction. There is no theorising, no useless attempts at explanation, no employment of imagination, no guesses at truth—all, in fact, arranged in order and leading slowly, but certainly, up to certain truth. Then the title of his work was complete, 'De Motu Cordis et Sanguinis,' and it was published in 1828, though since 1816 he had yearly demonstrated its truth before this College. The other work of Harvey's which in part remains to us is the 'Treatise on Generation.' Harvey was evidently early led, probably by the teaching of Aristotle and then by Fabricius, to watch the development of the embryo in the fowl's egg. He had completed a work on the generation of insects, the loss of which during the Civil Wars caused him great regret; and this and his remarks on the interest Charles I. took in his researches on the generation of deer show he must have been busy with the subject. It appears, indeed, to have had for him the same fascination it has had for all physiologists who have attempted this difficult problem. Harvey was less successful with it than he had been with the circulation of the blood. He brought to bear on it the same patient observation and unwearied industry, the same keen insight and unrivalled power, but he was in face of an inscrutable mystery. I will only remark that Harvey seems to me to have clearly caught sight of the mystery of generation, which we, with all or better powers of inquiry, are just as much unable to solve. All atttempts to explain this are mere concealments and subtleties of language. He had no microscope to carry him farther, as it has done us, though the only effect has been to throw the inscrutable a little back."

Sir William Jenner concluded with a sketch of the character and works of Dr. Parkes himself.

Correspondence.

VIVISECTION NON-MEDICAL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Allow me through your columns to call attention to the wholesale vivisection carried on in this, and I suppose other countries, by unauthorised persons, viz., cutting, or castration of male animals, and the cutting, or performance of ovariotomy on female pigs. I once witnessed a sow-cutter operating, and I must say that the operation, though skilfully performed, was attended with a very great amount of suffering to the unfortunate animals. Had these operations been performed for the good of humanity, what an outcry would be raised. I suppose the fact they are followed by an increase in money value of the mutilated animals does away with the inhumanity of the proceeding. I do not in the least wish to defend vivisection, as *unduly performed*, as in *some* medical schools, where lazy professors allow students to play pranks on dogs with phosphorus, but I think those good ladies and gentlemen who have raised this cry should just turn their humane eyes to what may and probably is carried on for the benefit of their own pockets.

Yours, faithfully,

ANTI-HUMBUG.

◆

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the MEDICAL PRESS AND CIRCULAR, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat, after it has passed through the post.

DR. BROWN-SEQUARD, of New York, will deliver three lectures "On Paralysis as an Effect of Brain Disease" at the Royal College of Physicians, London, on July 17, 19, and 21, at 5 o'clock each day. Members of the Profession admitted on presentation of card.

SENSIBLE HOGS.—In the coffee-plantations of Ceylon it has been customary to use the refuse left after the expression of cocoa-nut oil, as a fertiliser. Cocoa-nut cake is a *bonbon* to the palate of the wild hog, and consequently the coffee-planter used frequently to find his fields rooted up and destroyed, to the great detriment of his profits and of his morality. Recently, says the *Veterinary Journal*, the refuse of the castor-oil manufacturer has been substituted, with great relief. Its fertilising effect is very great, and the wild hog cares too much for his palate and intestinal tract to disturb the nauseous and poisonous compost.

Mr. B. J. will find the subject noticed in another column.

A COUNTRY PRACTITIONER.—We consider you have just grounds for action for breach of contract; it is, however, for you seriously to consider whether the individual concerned is worth "powder and shot."

APPOINTMENTS.

BRUMMITT, R., M.R.C.S.E., L.S.A.L., House-Surgeon to the Brighton and Hove Lying-in Institution.

CHESMAN, E., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer for the Llanbister District of the Knighton Union, Radnorshire.

CONNER, W., L.R.C.P.Ed., L.R.C.S.I., Medical Officer for the Dunsford and Tedburn St. Mary Districts of the St. Thomas Union, Exeter, and for the Cheriton Bishop District of the Crediton Union.

ELLIS, J. W., M.R.C.S.E., House-Surgeon to the Huntingdon County Hospital.

HANDS, A., L.R.C.P.L., M.R.C.S.E., Medical Officer for the newly-formed Wednesfield District of the Wolverhampton Union.

HARPER, G. S., L.R.C.P.L., M.R.C.S.E., House-Surgeon to the Belgrave Hospital for Children, Cumberland Street, Eccleston Square.

HAVILAND, A., M.R.C.S.E., reappointed Medical Officer of Health for the Brackley, Daventry, Hardingstone, Market Harborough, Newport-Pagnel, Northampton, Oundle, Pottersbury, Thrapston, Uppingham, and Wellingborough Rural, and Daventry, Hardingstone, and Oundle Urban Sanitary Districts.

HUGHES, H., M.R.C.S.E., reappointed Medical Officer of Health for the Bethesda Urban Sanitary District.

KEATS, W., L.K.Q.C.P.I. & L.M., Medical Officer, &c., for the Louisburgh Dispensary District of the Westport Union, co. Mayo.

KELLY, D. J., L.R.C.P.Ed. & L.M., L.R.C.S.I., Medical Officer, &c., for the Mullingar Dispensary District of the Mullingar Union, co. Westmeath.

MACCALL, W. N., M.D., Honorary Surgeon to the Clinical Hospital and Dispensary for Children, Manchester.

MARTIN, J., L.R.C.P.Ed., Medical Officer for the Alcester District and the Workhouse of the Alcester Union, Warwickshire.

POYNDER, G. F., M.R.C.S., House-Surgeon to Westminister Hospital.

THE NATURAL HISTORY OF PULMONARY CONSUMPTION.

By A. B. SHEPHERD, M.A., M.B., F.R.C.P.,
Physician to the Victoria Park Hospital for Diseases of the Chest; Assistant Physician to St. Mary's Hospital; &c.

LECTURE III.

MR. PRESIDENT, FELLOWS, AND GENTLEMEN,—Of the three forms of pulmonary consumption to which in my last lecture I drew your attention, the first is without doubt the most common; the second mainly at the other end of life, compared with the first, succeeds it in frequency; the last is so sufficiently represented that, even omitting the distinction I have attempted to make between the syphilitic type and the other two subdivisions, it has *long* ceased to be a mere pathological curiosity, and claims for itself a separate clinical position.

Differing widely in their first—if I may use the word—histological origin, continuing to hold throughout their course a pathological distinction, here and there, perhaps, delicately shaded off to one type or another, the pre-eminently cheesy form is never without some fibroid induration; the bronchitic and the fibroid, perhaps, never without catarrhal products; but their result being, in the end, the same destruction of breathing surface, their clinical symptoms are almost necessarily consistent, and repeat the same portraiture of a disease which is mainly one of innutrition and increasingly imperfect assimilation. And through the web of this disease runs no longer, for us at least, the one thread of a "tubercular" product—the first generalisation of imperfect knowledge and observation. Even those who most wish to keep up its specific character are driven to allow its unspecific form, and to plead that, like products of a higher type, its appearance varies with its age; or even still, as in seeking the philosopher's stone, to search for some particular cell-form which is to be the characteristic of "tubercle." But, however alike in their general symptoms and in the mode in which they lead to death, the three forms differ, not so much, perhaps, in their greater or less liability to catarrhal influence and catarrhal products, as in the qualities of hereditariness or acquirement. The common judgment, not only of scientific men, has long accepted the law of hereditary predisposition to the first form of phthisis; and the hereditary character remains the same, whether it be a tendency to repeated catarrh and its results in the bronchi and alveoli, or to a supposed growth of some low destruceive form called "tubercle." The *dispositio catarrhalis* of Morton (*op. cit.*, p. 77) was no empty name; the tendency even to catch cold, without any necessary phthisical process, is a matter of every-day occurrence. That very *dispositio catarrhalis* may be the only link between the two cases I quoted in my last lecture of a father dying probably of a slow bronchitic and emphysematous change in his lungs; the son, almost forty years younger, going in all likelihood more quickly to the grave with the cheesy degeneration of intra-alveolar and intrabronchial products, just as his grandfather before him had apparently gone. But, in the matter of hereditariness, the third form—that of fibroid change—can scarcely be said to agree with these two. Whatever be the poison, whether the more subtile one of alcohol or syphilis, or the rougher irritation of coal and grit, there is no evidence as yet to show that the tendency to fibroid change is one of hereditary character, although in some instances that character may be imitated by energies due to similarity of position or occupation. With the fibroid alteration found in the bodies of children affected with congenital syphilis, I have nothing to do here.

On the other hand, it is not sufficient to acknowledge the mere truth, in the ordinary form of phthisis, of a simple hereditary tendency. Not only are the writings of Sir Henry Holland, of Mr. Sedgwick and Mr. Darwin, but the every-day experience of life also, full of facts to prove that, as Mr. Sedgwick says (a) "in a very large number of cases of hereditary disease, evidence is to be found of some uniformly acting and controlling influence, which is strikingly manifested in the cases......where disease has been shown to have both its appointed sex and its appointed period to occur. So completely, indeed, has this latter fact forced itself upon the attention of the public, that we constantly find precautious being taken to guard individuals of a family prone to hereditary disease, such more particularly as phthisis, against what common observation has proved to be the dangerous period of their lives; for the friends in such cases hope that if this period can be got over safely, the danger may be less." The aid to prognosis which may be gained from the family history may be largely increased by the knowledge of something beyond the mere existence of a certain tendency: by a knowledge of the age at which, as well as of the sex in which, this tendency had revealed itself in the ancestor.

(a) *Med. Chir. Rev.*, July 1861, p. 213.

But this very knowledge is difficult to obtain. Very often the first sign which has drawn a patient's attention to his chest has been a spitting of blood; though very often, I am compelled to admit, the hæmoptysis is absent, and the cough and dyspnœa and loss of weight have awakened him to a sense of impending mischief. My notes go to show that, in cases under the age of thirty—I had almost said twenty-five—the prognosis is better where the hæmoptysis occurs than in those in which it is absent; and the reason of this might be found in the statement of a fact (*a*) by my former teacher, the late Dr. Barlow, as to the almost constant occurrence of bronchitis immediately before or contemporaneously with the commencement of phthisis; "that, whether the bronchitis be the cause of the phthisis, or the phthisis of the bronchitis the fact still remains the same, that there almost always exists a considerable hyperæmia of the bronchial mucous membrane at the commencement of phthisis"; and, to carry his assertion one step further, in some cases a considerable hyperæmia of the alveolar capillaries. And it is in these cases, very similar to, if not identical with, those classed by writers of different ages under "phthis ab hæmoptoe" that, the course of the disease is most favourable. It appears almost to stop short at the production, followed by resolution, of a local pneumonia, in which the escape of blood had something of a nature of a relief to over-distended blood-vessels; though of this local bleeding, in its further results, it would be, perhaps, too much to say simply with Cullen. (*b*) "It is, indeed, easy to conceive that a rupture of the vessels of the lungs, like that of the vessels of the nose, may be often healed, as the surgeons speak, by the first intention." It is somewhat astonishing at first sight, that the occurrence of hæmoptysis, supposed by the public to be very common at the commencement of true phthisis, is really not so. In most cases, the mischief has advanced some way before the bleeding, due probably to some degenerated blood-vessel, shows itself. And when we consider what really takes place in the catarrhal form of phthisis—that proliferation and caseation cause, or at any rate seem to cause, as the microscope shows us in such specimens as that diagram represents, impermeability and disappearance of the capillary vessels—the absence of any large amount of blood-spitting, I do not say throughout, but through a long portion of the phthisical process, is not to be wondered at. Of the copious hæmorrhages which take rise from a small aneurism in the wall of a cavity, or through the continuous oozing into the latter of blood from a degenerated vessel, I do not speak now. These are obviously of a dangerous character; but of the kind I have described I do not take so positively unfavourable a view. I may err in judging only from out-patient experience, from which I find that in cases coming to me for the first time there is a history of spitting of blood in only about half.

And this leads me to speak of the analysis I have made of my notes of 849 cases of phthisis among out-patients at the Victoria Park Hospital, not only as to its occurrence at various ages, but also as to sex, and to the seat, so far as shown, on their presenting themselves, by the physical signs.

The table of ages before you only illustrates once more the doctrine laid down by the Father of Medicine, "Φθίσις γίνεται μάλιστα ἡλικίῃσι τῇσιν ἀπὸ ὀκτωκαίδεκα ἐτέων μέχρι πέντε καὶ τριήκοντα ἐτέων," (*a*) and exactly reproduced by Sydenham, (*b*) "Phthisis autem invadit ab ætatis anno decimo octavo ad trigesimum quintum." I have omitted altogether those cases which, presenting only dyspeptic symptoms, had no signs of mischief in the lungs. The large majority of cases, as you may see, were between the ages of fifteen and forty.

There is one other fact illustrated by this table which has some bearing on a rule laid down by some insurance-officers as to the possibility of phthisis of the hereditary type being extinct after the age of forty-five. In this table, there are fifty-six males and twenty-nine females, making a total of eighty-six persons, or 61 per cent., attacked with a pulmonary disease, whether it be the ordinary cheesy form first revealing itself at this later age, or that form of chronic bronchitis which, leaving its own type of winter-cough, has taken on the form of a continuously emaciating phthisis.

As to the seat of change in these patients, the result of analysis does not differ very much from those obtained by, at any rate, later writers on the subject. Laennec believed that the right lung was more frequently affected than the left; while Louis found the disease confined in five instances to the left lung, and in two only to the right; and, as he observed the advance of the disease from above downwards especially marked in twenty-eight cases on the left side, and in ten only on the right, he concluded that the left lung was by preference the seat of change. Dr. Hughes, in a paper in the *Guy's Hospital Reports* for 1842, is probably very near the truth when in giving his own results of 116 cases on the left side, against 89 cases on the right, he declares his conviction (p. 249) that this difference is so trifling as to be altogether unworthy of notice in reference to diagnosis; and I think he might have gone further, and added "prognosis." Dr. Cotton (*c*) finding the same preference of the left over the right lung, comes to the same conclusion in almost the same words: the difference "is so small as to render it a subject of curiosity only, and not of the slightest value either in the diagnosis or treatment of consumption." My own numbers give the following results. Of 424 cases, the affection was present in both in 151 cases, 77 males and 74 females, confined to the right lung in 120, and to the left in 153. The difference in numbers between left and right was more marked in men than in women: in 104 cases in which both lungs were affected, the right was most so in 48, the left in 55. As to sex, the larger number of men affected, as compared with women, points probably to the change of temperature and weather, and to some extent to other risks of occupation, to which men are more exposed. At the same time, there is a larger fatality from the disease among men whose work compels day-long confinement indoors. In a table published among others relating mainly to conclusions drawn up for an insurance-office by Mr. Alfred Smee, jun., there is one which shows the influence of occupation in the cases of 291 men who died in the Victoria Park Hospital of pulmonary disease. The occupation was in 150 cases indoor, in 41 mixed, and in 100 outdoor.

I had drawn up, sir, a large number of tables based on the records of cases enumerated in that one list, not only with respect to age, sex, and occupation, and the so-called different stages of the disease, on which last I am disposed to lay no great stress, but also in reference to the supposed influence of various concomitant affections, and the influ-

(*c*) *On Consumption, &c.*, 1858, . 1

ences of temperature and weather; but, in going over them for the last time before I brought them here, I found them of such unchanging dulness, that I decided, with your permission, and with a view to relieve the tedium which those who do me the honour to listen to me cannot but feel, that it would be better to embody such results as I could offer in the general matter of this lecture, and omit the statistics on which they were founded, even though such a course of proceeding would necessarily cause a shortening of the time prescribed for me.

But to my mind the majority of these statistical tables are merely curiosities. They have no bearing in the case of some individual patient who comes to us for advice; they might not have on him the same evil effect, perhaps, which the result of calculations as to the mean duration of phthisis by different observers might have. In giving a list of averages of duration, in which the shortest time, according to Louis and Bayle, is twenty-three, and the longest, according to Dr. Williams, (a) forty-eight months, Dr. Pollock (b) is much more hopeful in the statement that Portal considered phthisis might last "from eleven days to forty years, and he is certainly nearer the mark than any other authority." On this point, Morton himself observes: "Hinc fit, quod phthisis vulgo tam male audiat, ac si esset morbus naturâ suâ prorsus incurabilis, quum (quantum ego longâ experimentiâ edoctus scio) æquè certam curationem, atque alii morbi. admittat, modo debitâ methodo, satis tempestivè tractetur." (*Op. cit.*, p. 171.) It is an odd thing that one (c) of the upholders of the inflammatory origin of phthisis should have held also the possibility of its cure—that is to say, that it was not absolutely hopeless; just as Niemeyer, writing in these later times, and holding the same theory, has as strongly asserted; while the champion of the "tubercular" theory held and hold with Laennec that "the tubercular affection is, like cancerous affections, absolutely incurable" (*op. cit.*, vol. i., p. 581); or in the stronger language of the next paragraph, "that the observations of Bayle and myself show that the idea of the possibility of curing phthisis is an illusion." I dare not yet speak of my own experience. I do but see from time to time cases of the chronic form of cheesy phthisis, holding on the almost even tenor of their way, with but little, if indeed any, change in physical signs; and in these cases I cannot but suppose that, as in other chronic forms of disease, the body or the constitution—call it as you will—becomes as it were habituated to the changed circumstances of life, which make up for it, as a living whole, its normal standard.

Holding, therefore, almost the contradictory of Cullen (*op. cit.*, p. 100), that "phthisis in consequence of pneumonic inflammation is that which occurs most rarely in this climate," I am able, with Morton and Broussais and Niemeyer, to have a larger hope; and though, with Cullen (*op. cit.*, p. 381), I am ready to say that "nothing should allow us to neglect any appearance of catarrh, as is too frequently done, for it may be the beginning of a phthisis, which is mistaken for a genuine catarrh, or that even as a catarrh continuing long, it may produce a phthisis"; and though with Hippocrates (*d*) "τὸ φθινόπωρον τοῖσι φθίνουσι κακόν," I am compelled to say, from my experience at Victoria Park Hospital, that while in the warmth and even heat of summer, all my bronchitic patients are better, those who are suffering from phthisis are very much worse, partly because the heat calls for more work from the injured respiratory organ; partly because, as even in the healthiest of us, it throws the power of assimilation, and therefore of nutrition, somewhat into abeyance. The advice recorded in Wepfer's observations (*op. cit.*, p. 435), though difficult to follow, because its conditions are difficult to obtain, is probably true in regard to the temperature best suited for phthisical patients: "Ægro nobilissimo aë convenit temperatissimus id est, nec calidior, nec frigidior, nec siccior, nec humidior ideo et æstum solis nimium et aerem vespertinum et pluvium vitet." (*a*)

To be continued.

(a) This average has been more recently (Williams, *Pulmonary Consumption*, 1871, p. 306) raised to, roughly, eight years.

◆

ON THE ETIOLOGY AND TREATMENT OF SCROFULOUS OPHTHALMIA. (*b*)

By H. Cripps Lawrence, L.R.C.P. Lond., &c.

At present the scrofulous diathesis is the polar star which sanctions, almost of necessity, but one line of treatment, quinine, iron, cod-liver oil and various counter-irritation. The clinical results thereof are by no means uniformly satisfactory. The assumption, for it can be called at present but little more, that the scrofulous cachexy is virtually the *fons et origo mali*, is no doubt true; and it would be presumptuous to question even this uncertainty unless prepared to offer something definite in its place. I do however venture to believe with the evidence we have from anatomical and physiological researches, of an intimate connection between the sympathetic nervous system and the various factors of the complex phenomena associated with scrofulous ophthalmia, that a series of carefully conducted observations upon the following points will yield something definite respecting the etiology and hence touching the treatment of the affection:—

1. The sequential order and value of the various symptoms of scrofulous ophthalmia.
2. The ophthalmoscopic appearances of the retina during life.
3. The sphygmographic evidence of the state of the general circulation.
4. The post-mortem condition of the superior cervical ganglion of the sympathetic, especially as examined microscopically.
5. The results of galvanisation of the superior cervical ganglion of the sympathetic.

The line of thought which evidently led Dr. Althaus to doubt the varying statements and views in relation to scrivener's palsy, appears to me worthy of note in relation to any investigations respecting phlyctenular ophthalmia.

The thought may be erroneous, but one feels justified in suggesting that possibly some special imperfect nutrition, probably, but not of necessity, of a scrofulous nature, involves the superior cervical ganglion of the sympathetic, and may hereafter serve to explain the locus and proximate causation of those phenomena we now term scrofulous ophthalmia. In other words, a search for a nerve location of the disease is desirable. That scrivener's palsy does more or less directly trace its origin from some morbid condition of the superior cervical ganglion is presumably true, judging from the effects of the continuous galvanic current. Dr. Althaus employs galvanisation on the principle of "the disease being in the upper part of the spinal axis"...coupled with a "knowledge that the cervical sympathetic nerve has a powerful influence upon the nutrition of the whole nervous system."

The manifold relationships of the superior cervical ganglion of the sympathetic, serve to explain numerous associations with other nerve centres; among these are nerves especially concerned in the etiology of scrofulous ophthalmia.

(*a*) This opinion of the consultant, amusing and full of common sense throughout, concludes with words equally difficult, but equally true for the consumptive patient to take to heart, were it only possible: "Vitet mœrorem atque quemvis alium animi affectum gravem."

(*b*) Read before the Harveian Society April 6th, 1876.

(c) With regard to treatment, let me briefly narrate my own limited experience.

The marked digestive derangement has benefited from a mercurial purge, followed by a course of non-mercurial aperients until the evacuations become normal. Next a plain nourishing and unstimulating diet, to which milk contributes largely, is beneficial. Meat should not be given too freely. Most of the patients are ill-nourished when scrofulous ophthalmia manifests itself; partly from poverty, partly from digestive imperfections: to feed these too generously virtually promotes starvation, the fuel becomes excessive for the combustion power of the invalid.

Cod-liver oil requires regulation in use. Instead of regarding it as a specific, my own experience has led me to consider it hurtful in some cases; the cases for its use and non-use may be differentiated thus, as Sir William Lawrence and Niemeyer have noted. First the "torpid" constitutions, who are clumsy and thick-set in build, and exhibit a tumid upper-lip and enlarged nose, and have abundance of adipose tissue; by these cod-oil is not required, and it may prove injurious to them; while secondly, the "erethitic," with slender frame, lack of fat, and accelerated pulse and over-active nervous system, largely benefit from the use of cod-liver oil. These cases have procured for it the name of an anti-scrofulous remedy (Niemeyer).

The photophobia has been relieved at first by the use of bromide of potassium, and the relief maintained by the administration of quinine. Quinine employed after potassium bromide has appeared more efficacious than when used alone. Relapses of intolerance of light have yielded to similar treatment.

Fresh air, and plenty of it, is imperative. Cold shower-baths in summer, sponging with tepid sea-salt water in winter, have proved valuable auxiliaries.

For local treatment a green shade, made like the peak of a rifle cap, is preferable to one fitting close to the eyes—the latter being injurious. Padding of the eye with cotton wool to prevent friction of the lids appears to me neither necessary nor advantageous, equally good if not better results having followed frequent poppy fomentation instead, allowing free exposure to air, with shade from light.

When the acute symptoms have subsided the utmost possible benefit has ensued upon the use of poppy fomentation used as a douche to the eye, at first warm, then tepid, ultimately cold. The spasm of the orbicularis oculi seems to be much lessened thereby.

Counter-irritation in the form of linimentum iodi painted behind the ear is preferable to blistering. Scrofulous constitutions resent blisters, secondary cutaneous eruptions and swelling of the neighbouring glands being apt to follow. Frequency of counter-irritation however, short of producing breach of skin and glandular enlargement, seems not only indicated, but is found practically to be very useful.

Nitrate of silver has proved itself injurious when applied to the conjunctiva in scrofulous ophthalmia, and solution of atropine less useful in allaying irritation temporarily than frequent anodyne fomentation. Atropine should be reserved to ensure dilatation of the pupil when necessary.

Iron is preferable to quinine in marked anæmia, but I have not sufficient evidence to prove its greater efficacy over quinine in promoting repair and nutrition in ulceration of the cornea, as some authors assert, while quinine exerts a marked effect in lessening the photophobia scrofulosa.

In conditions of extreme blepharospasm, photophobia, and epiphora, the eyes should be examined under chloroform and belladonna given as Mr. Power has suggested, "as a stimulant upon the sympathetic system of nerves, and through this upon the smaller vessels."

A case of extreme blepharospasm under my care seemed likely to require division of the orbicularis at the external canthus, but escaped this procedure owing to the marked benefit received from douching with cold poppy, fomentation, and shower-baths, the face being held upwards to receive the full force of the shower.

If the superior cervical ganglion of the sympathetic be hereafter proved to hold a position of primary importance in the etiology of scrofulous or phlyctenular ophthalmia, I need hardly add that I shall look to the continuous galvanic current to supply a potent therapeutic agent. Galvanisation is likely to prove of value not only as an auxiliary to other remedies, but it bids fair itself to expedite repair through its action on the cervical sympathetic, by promoting nutrition in structures very prone to chronic degeneration. Nay, more, by cutting through the chain of morbid phenomena which produce the condition named "chronic inflammation," galvanisation may even serve to prevent its occurrence.

A brief record of the two following cases have an interest in reference to the etiology and treatment of scrofulous ophthalmia :—

Case I.—E., æt. 10, came under my care at the London Diocesan Deaconess' Institution, owing to the kindness of Dr. J. W. Langmore. Upon admission there was marked commencing ulceration of both corneæ, some conjunctival congestion especially marked on the lower lids, scattered vesicles on the palpebral and ocular conjunctiva, a phlyctenula close to the inner margin of the right cornea, with a fasciculus of vessels running from the inner angle of the eye towards the cornea; photophobia and slight blepharospasm; the treatment was by good plain food and plenty of fresh air. No internal remedies; but locally the following means were used:—A drop of a solution of perchloride of mercury (gr. ss. ad ℥i.) was dropped into each eye night and morning. The effect of this was to increase the conjunctival congestion and photophobia, and to induce ciliary neuralgia. After two or three days poppy fomentation was employed warm, and the linimentum iodi was painted behind the ears every other night. At the end of a week a marked improvement followed. I was much tempted to treat the case with iron and cod-liver oil, for the patient was both erethitic and anæmic. In one month the eyes were practically well, and the girl had become for her sleek and rosy.

Whilst preparing this paper I was unable to obtain a case upon which to try the effect of galvanisation of the superior cervical ganglion of the sympathetic, but in April last Dr. Dawson Nesbitt kindly placed a patient under my care for treatment by galvanisation.

Case II.—J. N., æt. 9 years. No history of phthisis or scrofula in the family. Father's family rheumatic. One brother and two sisters are living. Three brothers died in infancy—one at birth, of hydrocephalus, necessitating craniotomy.

J. N. was breast-fed for three months. Primary dentition was normal. She had rheumatic fever when seven years old, but no other illness till the recent outbreak of scrofulous ophthalmia, which commenced early in March, 1876. No advice was sought until April, 1876, when the condition was as follows :—

Presents strumous aspect, photophobia slight, but light does not cause pain, blepharospasm and slight epiphora. A well-marked phlyctenula is to be seen at the lower and outer margin of the right cornea, with a fasciculus of vessels running toward the phlyctenula. Vesicles are apparent in the furrow between the lower lid and ocular conjunctiva, and on the margin of the lower lid. Galvanisation was applied by means of Weiss's continuous battery, employing a current of eighteen cells, the positive pole being placed over the transverse process of the seventh cervical vertebra, and the negative pole applied to the stylo-mastoid fossa for five minutes. After this the negative pole was applied with forty or fifty interruptions around the right orbicularis oculi. The visible immediate effect of this was to cause a marked contraction of the conjunctival vessels, and the blepharospasm was lessened. A green shade was ordered, and the eyes only to be bathed with tepid milk and water. No internal medicine.

April 3rd.—Photophobia had increased, but the blepharospasm and epiphora were less. The conjunctivitis was increased, and a slight haze fringed the lower margin of the cornea, at and adjacent to the site of the phlyctenula.

On April 4th, much the same condition, but the phlyctenula was less marked, as also the vessels leading up to it; the conjunctival vessels congested, and right pupil rather contracted.

On April 6th, less, but still marked conjunctival congestion, photophobia less, but circumorbital pain complained of; no blepharospasm; the fasciculus of vessels going to the phlyctenula replacd by a reticulated network of conjunctival vessels; the phlyctenula is decidedly smaller; a faint sclerotic zone surrounds the cornea.

On April 7th, a little vinum ipecacuanhæ was ordered for a cough.

On April 10th, all symptoms improved, and the patient able to open the eye well.

April 12th, three vessels run up to the site of the phlyctenula, which latter has almost disappeared, leaving a slight haze of the cornea. No pain, blepharospasm, or epiphora; slight photophobia.

On April 17th, convalescent.

The left eye was unaffected.

The galvanisation was repeated daily, excepting Sundays, for the first week, then every other day the following week, in the manner described above.

Although the case is single, it seems to bear out the line of thought expressed in the paper, that galvanisation of the superior cervical ganglion of the sympathetic may yield useful results in the treatment of scrofulous ophthalmia. The temporary increase of conjunctivitis which ensued upon the earlier applications of the current is interesting when compared with the results obtained by Dr. Sinitzen from evulsion of the superior cervical ganglion.

In reference to the etiology as well as the treatment of scrofulous ophthalmia, there is still much need to discriminate between the essential and the accidental—much opportunity for investigation and experimental research how far constitutional and local treatment are respectively necessary; still much required to decide whether the *post hoc* or the *propter hoc* avails in treatment.

◆

UNUSUAL SEQUELS OF SCARLET FEVER.

By M. J. Malone, M.D.,
Fellow and Examiner, Royal College of Surgeons in Ireland;
Physician to Limerick Lying-in Hospital, &c.

The following account of some of the more uncommon sequels of scarlatina may, I trust, be found interesting to the readers of the Medical Press.

In October, 1875, a lady called on me accompanied by her son, a boy about nine years old, who complained of a soreness in the throat. On examination the tonsils were found to be somewhat swollen, and the surrounding mucous membrane inflamed. The pulse was but little increased in frequency, and the skin felt so cool that I did not think it necessary to take his temperature with a thermometer. There were several cases of tonsillitis in Limerick at the time (indeed I had but just returned from seeing one), but there had not been a single case of scarlatina for a considerable period, so far as I then knew, or could subsequently ascertain. In view of these facts I told the mother that I considered the case one of simple quinsy, and prescribed a chlorate of potass mixture and saline aperient. I said the boy should be kept in doors, and that if any efflorescence appeared I should be informed at once. In two days the mother called to say that a slight rash had come out on the chest, but that the boy was not otherwise worse. I happened at the time to be just leaving home for Dublin, so could only give general instructions, and refer her to a professional friend who would see my patients in my absence. On my return, after a few days, I visited the boy, and found he had gone on so satisfactorily that the doctor had not been sent for. The rash had disappeared, his urine was depositing a considerable quantity of lithates, but contained no albumen, and he was nearly quite well. I was not sure whether this case was one of scarlatina, or of roseola coincident with tonsillitis. The mildness of the attack, and the total absence of scarlatina from the locality inclined me, on the whole, to the latter opinion; and I had not seen the rash.

After two or three days, however, I was asked to visit the boy's sister, aged ten years, whose stomach had sickened at school. I found her in bed, feverish, and complaining of headache. She did not suffer from the throat, but the pharynx seemed conjested on inspection. These symptoms were, of course, very suspicious of scarlatina, but not positively pathognomonic. A diaphoretic was ordered, and on the following day any doubt was removed by the appearance of the typical efflorescence. This patient had a mild attack of the disease, but the convalescence was protracted. There was a trace of albumen present in the urine for a considerable time, but its density was normal, and there was no œdema. Pruritus was complained of, and was relieved by the inunction of bacon fat. A slight, puffy swelling appeared in the left side of neck, near the angle of the lower jaw. There was great local tenderness, but not much appearance of inflammation, and the head was drawn down a little, and turned to that side. The mother thought this might have arisen from the child's head having rested on the pillow inclined laterally; but that was not probable. It seemed to me to be an example of the peculiar form of torticollis first described by the late Mr. O'Ferrall in his letter to Dr. Graves on the subject of scarlatina; but there had been none of the "marked and prolonged difficulty of deglutition, as a symptom of the disease," which was present in the cases he describes. I believed the affection to be due to a circumscribed inflammation of the sterno-mastoid muscle, but local abstraction of blood did not seem necessary, and I should'nt think of giving mercury, as was done in the cases referred to. The only treatment I adopted was the application of a little of the iodide of cadmium ointment; and though the condition remained for several days, and the part was so tender that examination was made with difficulty, a complete recovery ensued.

In the meantime a third child, three years old, got an attack. He proved so impatient of the least interference that it was impossible to do more than nurse him in his cot. He made a good recovery. From the commencement I had all the children kept from school, but it was not convenient to the parents to send any of them from home. No prophylactic treatment was adopted, and yet three out of six children escaped infection. Had I used belladonna the result would have seemed a satisfactory example of the preventive power of that drug.

While I was treating the girl the boy got what at first appeared to be a relapse. He felt ill, his temperature went up, and he had to keep the bed. A characteristic, inflammatory swelling of his knees, ankles, and wrists, successively, very soon revealed the nature of this new ailment, an attack of acute articular rheumatism. There had been premonitory pains in the joints for some few days previous. Alkalies with diuretics were administered, and the affected parts painted with tincture of aconite, and then covered with wadding. He was much relieved by this treatment. The inflammation, as usual, changed rapidly from joint to joint, and in about a week the patient was able to walk about. His sister and he were then ordered tonic medecines, and as they were fairly convalescent I discontinued attendance, requesting that any symptoms of dropsy might be at once reported.

The little patients got on very well, and after a suitable interval were able to return to school. Towards the end of February, nineteen weeks after the inception of the scarlatina, the mother called on me to say that she feared the boy was suffering from symptoms of paralysis. He dragged his right leg after him in walking, and used his right hand in a very awkward manner. He had driven with her to my house, and as he entered my study he certainly looked like one suffering from hemiplegia. An examination, however, showed that there was no paralysis, but marked loss of directive power over the muscles. The hand, too, moved spasmodically, and he could not control its motion. When asked to put out his tongue he jerked it out, and as rapidly withdrew it. It was evident that he was affected with hemi-chorea of the right side, and I was happy to be able to assure his mother that there was no danger of paralysis, properly so called. As he looked anæmic I examined his heart, and was not surprised to find a loud systolic bellows murmur over the aortic valves. There was also a venous hum in the neck, but not so well marked as that frequently found in chlorotic females. I prescribed iron and valerian, with occassional purgatives, a cold bath each morning, followed by friction of the skin; and as much directed exercise as possible of the affected limbs, as at tops and ball playing. I continued to see the patient from time to time, and was gratified to notice a perceptible, though gradual, improvement in the symptoms.

Early in March my attention was asked to the girl. She had been quite well and going to school daily, when she was noticed to suffer a rather sudden impairment of vision. She had been well able to read very small print heretofore, but now, when I showed the title-page of the "Medical Directory," it was only the largest letters that she could recognise. She threw back her head, and held the book at such a constant distance that I at once formed the opinion that she suffered from loss of accommodation—paralysis of the ciliary muscles. One of the parents had acquired a weakness of vision at about the same age, which proved to be permanent, and consequently much anxiety was felt about the child's state. To outward view the eyes looked quite healthy. I examined the interiors with the opthalmoscope, as well as I could without dilating the pupils, as I would not use atropine in view of the diagnosis, since it would certainly intensify the symptoms. The humous appeared quite transparent, and I could detect no sign of disease. I explained to the parents that it was the focussing arrangement of the eye that the child had lost control over, from delicacy of constitution; and expressed a confident hope that perfect rest of the organs, with a little strengthening medicine, and general hygienic adjuvants, would bring her round soon again. My instructions were faithfully carried out, and I am happy to say with perfect success. In four or five weeks the eyes had acquired their normal power; and both this patient and her brother are now quite well. She can easily read the smallest print, and I detect no trace of valvular or venous murmurs in him.

Acute rheumatism is a recognised though not common sequel of scarlet fever, especially of mild cases. The impairment of the functions of the skin during the period of desquamation is probably a considerable element in its causation when it does occur. The pathological relations of rheumatism and chorea have been also long observed. The occurrence of the latter, especially in a boy, after an attack of rheumatic fever, would seem to be something more than a *post hoc* coincidence. Yet the anæmia produced by the two preceding illnesses had, no doubt, much to do in its appearance. There were no worms in the alimentary canal, nor was the chorea preceded by any marked mental impression. When this disease is confined to one side the left appears to be that more commonly engaged, but in this case it was the right side exclusively that was affected. After an interval of three and a-half months there now remains only a slight awkwardness in using the right hand which is gradually disappearing.

The paralysis of the ciliary muscles, in the girl, was perhaps the most curious and unusual of these sequels. I do not remember having read of its occurrance after scarlatina. I believe it is most frequently observed during convalescence from diphtheria, which might be expected from the frequency of different forms of paralysis after that disease. This was the first case of the affection I had seen, but its diagnosis could offer little difficulty on careful examination. The transparency of the eye and sensibility of retina were evidently unimpaired, but the near point of vision was removed from the inability of the lens to focus divergent rays. The head was consequently thrown back when the patient tried to read a book held in the hands. A suitably convex lens would, do doubt, remedy the defect, but rest of the eyes is an essential point in the treatment. The mobility of the iris was not sensibly diminished.

Another point of interest in these cases is the apparent spontaneity of the disease in carefully-tended children residing in a healthful suburb of the city. It did not spread. Several weeks subsequently a case occurred in the dispensary practice of my friend, Dr. Carey, in a locality at least a mile distant from the residence of my patients. Still later on I saw some bad cases in a crowded and fetid lane. One, at least, proved fatal; but the parents unfortunately too often resist any attempt to have the children sent to the well-ventilated wards of our union hospital. Scarlatina, unlike typhus, will, however spread in spite of ventilation. Indeed, anything that may convey an epithelial scale may also convey the contagia. Milk, articles of clothing sent long distances, and even newspapers transmitted by post, have been known to act as vehicles of the infections; and this, of course, renders prophylaxis a matter of extreme difficulty. Personal disinfection of the patient, especially during the desquamative stage, would seem to be the most rational means of accomplishing this end.

I have ventured to offer the foregoing paper for publication, as I think it is not often so many curious sequels of scarlet fever come under the observation of the physician in so limited a number of cases.

◆

OBSERVATIONS ON BOX (BUXUS SEMPERVIRENS); WITH SPECIAL REFERENCE TO THE TRUE NATURE OF TETANUS. (a)

By Sydney Ringer, M.D.,
Professor of Therapeutics at University College; and
William Murrell, L.R.C.P.,
Demonstrator of Anatomy at University College.

The authors were induced to undertake an investigation of the physiological action of box from the frequency with which it has been recommended in the treatment of hydrophobia. The views expressed as to the nature of box are founded partly on experiments made on frogs under buxus, and partly on the results of an investigation of the properties of gelseminum.

The paper is divided into three parts. I. Introductory: the history of box, especially with reference to its use by the older writers on medicine in the treatment of hydrophobia. 2. Experimental: the action of box on the nervous system of frogs. 3. A consideration of the true nature of tetanus, illustrated by experiments on reflex action.

The first part, being purely introductory and historical, requires no detailed notice. In the second part details are given of experiments performed on frogs before or after the injection of box. It is shown that that drug causes paralysis and then tetanus. The conclusions resulting from these observations are—(1) that the initial paralysis is cerebral in its origin; (2) that the drug also produces paralysis and tetanus by its action on the spinal cord; (3) that the sensory and motor nerves and the muscles are unaffected. In the third portion of the paper the authors discuss the nature of tetanus. They were led by their experiments to the conclusion that the theory of tetanus being due to an excited condition of the cord is erroneous and misleading. They, on the contrary, regard tetanus as an expression of depression or paralysis of the cord; they show that if the symptoms induced by the injection of strychnine were due to mere stimulation of the cord normal reflex action would be not only retained, but would be more vigorously performed. Such, however, is not the case; for in frogs poisoned by this drug irritation of the posterior extremities induces, not a co-ordinated movement resulting in the withdrawal of the leg, but a general contraction of the muscles of the body, causing powerful extension of the limbs. This is regarded as evidence that the impression, instead of being limited in its action to that portion of the cord on which it impinges, is widely diffused throughout its motor tract, the increased diffusibility being caused by diminished resistance; in other words, by depression or paralysis. It has been stated that box causes, first paralysis of the limbs and then tetanus. Such a condition, according to existing theories, must be due to a very singular combination of circumstances—viz., depression of the reflex function of the cord, followed by stimulation; the stimulation continuing simultaneously with a rapid impairment of normal reflex action. It would, the authors consider, be more rational to conclude that the drug first depresses the cord so as to diminish reflex action, and then causes tetanus by paralysing its resistive force. In health, when an afferent stimulus is conducted along a nerve, its effects are limited; but tetanising agents, by weakening or destroying the resistive power of the cord, facilitate the diffusion of the impulse, and favour the excessive generation of nervous force. It is obvious that, as box weakens reflex action before producing tetanus, a larger dose is required to lessen the resistance of the cord than to diminish the reflex function, and the absorption of a larger quantity of the drug is necessary for the production of tetanus. In the case of frogs poisoned by box, even when the tetanus is very powerful, the paroxysms after a time grow weaker and weaker, till finally they fade away in a mere quiver of the muscles. If tetanus were due to excitement or stimulation of the cord, it is obvious that, as this condition subsides, the tetanic movements should gradually decline, and at last subside, with the restoration of normal reflex action. But, as a matter of fact, this order is never observed, for the tetanic movements continue to grow weaker and weaker, till at last all movement ceases and general paralysis ensues. In those cases in which, during the tetanic paroxysm, the muscular contraction is not greater, or is even less, than an ordinary reflex act, it must perforce be admitted that the tetanus is not dependent on an excited condition of the cord, but solely on its lessened resistance enabling an impression to diffuse itself through the greater part or the whole of the motor tract. It was found that in box-poisoning a strong irritation often excited tetanus, whilst a feeble stimulus produced only a weakened reflex action. It is contended that the explanation of this is that in these cases the resistive power of the cord is but slightly diminished, so that a strong impulse can diffuse itself whilst a weaker is confined to that part of the cord naturally associated with the stimulated nerve. Moreover, soon after the injection the tetanus is limited to the irritated limb, because, the resistive power being but slightly weakened, the diffusion of the impression through the cord is correspondingly limited; but as absorption continues the resistive power grows weaker and weaker, and the impressions diffuse themselves more readily and widely, until at last the whole or a greater part of the body becomes tetanised. In the course of some observations made with the view of determining the duration of reflex action in frogs after division of the medulla, the authors obtained some curious and unexpected results, which strikingly confirm their theory of tetanus. They found in unpoisoned frogs, whose brains had been destroyed by pithing, that soon after the commencing decline of reflex action a condition of tetanus was observable. The tetanic symptoms were readily produced by gently lifting the animal and allowing it to fall on its back, or by striking it with the forceps on the cervical region. The tetanus varies considerably in its intensity in different cases. Sometimes the legs, though strongly shot out, were again quickly withdrawn; but in several instances the paroxysms, when at their height, lasted from a quarter of a minute to a minute, the limbs being so rigidly extended that the animal could be taken up by its hind legs and held out horizontally. In each of these paroxysms there was a far greater discharge of nervous force than occurs in a normal vigorous reflex act, and therefore, according to current views, the cord would be said to be excited. That this explanation is inadmissible is shown by the fact that tetanus is at its height at a time when the normal reflex action is much impaired and immediately before its total abolition. The duration of tetanus varies, being dependent on the persistence of normal reflex action. The details are given of experiments which show that this tetanus is purely spinal in its origin, and an explanation is offered of the mode of production of the phenomena. Soon after systemic death the cord becomes depressed, and, consequently, reflex action is weakened; but with depression of reflex action there is diminution of the resistive power of the cord, whereby impressions ceased to be restricted to that portion of the cord on which they impinge, and, spreading widely, cause tetanic movements instead of a normal reflex act. At first, before there is much weakening of the resistance of the cord, a slight stimulation induces a natural reflex action, but as depression of the cord progresses, and the resistive power grows weaker, the tetanic movements become more powerful and are more readily induced. Moreover, it was found in these frogs, at a time when strong irritation was required to excite even slight tetanus, that a very powerful stimulation, such as a succession of blows on the back, would induce tetanus, a condition which was immediately followed by diminished intensity of the ordinary reflex phenomena. The correct interpretation of these facts is that the blows depress or break down the resistive power of the cord so as to weaken normal reflex action, and, by allowing the irritation to diffuse itself more widely, to cause increased tetanus. This view is confirmed by the fact that on striking vigorously and repeatedly a living and perfectly normal frog between the shoulders there is excited at first a simple reflex act, but subsequently the posterior limbs after each blow are shot out in a manner which is distinctly tetanic, although the movements are far less energetic than when these phenomena are observed in pithed frogs on the decline of reflex action. This tetaniform condition occurs only when the shock of the blows has so depressed the cord that all voluntary and reflex action is for the time abolished. The authors, whilst regarding tetanus in all forms simply as an indication of a diminution in the resistive power of the cord, point out that some tetanising agents, such as strychnia, leave the reflex action unimpaired, whilst others depress both the resistive and the reflex power. Some agents—for example, gelseminum—depress the reflex function more than the resistive power, causing considerable paralysis but slight tetanus. Others—such as box—depress the resistive power early and markedly, and subsequently and in a minor degree the reflex function, the result being strong tetanus with slight paralysis. These views on tetanus throw light on the effects of slight chemical modifications of a drug on its physiological action. It is obvious that nerves in their constitution must differ from one another and from the brain and spinal cord, since a given poison may effect one part only, leaving the others *in statu quo*. Strychnia excites powerful tetanus and in large doses depresses simultaneously the motor nerves, but if converted into an ethyl compound it no longer tetanises, but powerfully paralyses the ends of the motor nerves. By this change in its composition its physiological action is not reversed, for as strychnia it paralyses the constraining or resistive power of the cord, whilst as ethyl-strychnia it paralysis the motor nerves. It is not converted from a stimulant into a depressant, but with the change in its chemical affinities its sphere of action is shifted and it paralyses the motor nerves instead of the resistive power of the cord.

INAUGURAL MEDICAL ADDRESS ON THE OPENING OF ST. MICHAEL'S HOSPITAL, KINGSTOWN.

By M. A. Boyd, F.R.C.S.I.,
Surgeon to the Hospital.

This hospital is intended for the reception of every species of disease, surgical and medical, and at all hours will be open for the reception of accidents, which will be attended promptly by a house surgeon or resident, whose duty will be to remain constantly on the premises.

The wards for the reception of patients are four in number, two large and two medium size; the former are 56 feet in length, 24 feet in breadth, and 16 feet high, and will contain 14 beds each, and allow about 1,600 cubic feet of air to each patient. The two smaller wards are each 35 feet long, 23 feet wide, and 12 feet high, and will contain 6 beds each, with the same number of cubic feet of air to each bed. At the rear of each ward runs a corridor, well ventilated and lighted, and communicating with the wards by ventilators on the most improved principle of hospital construction. In fact, the hospital is perfect in every detail, and nothing is left wanting to make it a clinical institution of the first-class, into whose wards there will be free admission for patients of every creed and students of every school to study the science of clinical medicine and surgery in all its details, and no stone will be left unturned on the part of its staff to impart to them all the necessary instruction required to make them diligent students, accurate in acquiring a knowledge of disease in its various aspects, and to lay before them the many appliances, surgical and medical, which science is every day calling to its aid in the investigation of disease, for strange as it may appear to many who are unacquainted with its workings, the science of medicine is still only in its infancy, notwithstanding the hundreds of years during which medicine has been cultivated, notwithstanding the numerous sciences which constitute what we call the science of medicine, the term science is scarcely applicable to that department of it which relates to the treatment of disease by means of remedies. We have in the recorded experience of past and present generations an immense accumulation of material, valuable and the reverse, relating to the influence of drugs on the progress of disease, but we are sadly in want of accurate generalisation and the establishment of definite and precise laws as to their efficiency and employment.

"To those who are acquainted with the successive stages through which Medicine has passed, and who know the modes of thought and the methods of investigation which are followed by her most active promoters, it will not appear that we are indulging in vain hopes or idle speculations when we assert that the time is not far distant when she may legitimately rank as a science. Many indeed will believe that we are doing her scant justice in questioning her claims to such a place. It will however only be when general laws connecting disease with health, and establishing a perfectly rational system of therapeutics that shall be applicable to the whole body of medical facts, that the term science will be legitimately applicable to medicine, experimental pathology, studying the synthesis of disease, and experimental pharmacology, localising the action of drugs on the tissues and organs of the body, are fast following in the steps of the rapidly advancing science of physiology, of which they are but departments, and young though they are, are furnishing the materials for a real science of medicine."

In recent years, by the application of instruments of precision and exact methods, our knowledge of the circulation, respiration, nervous system, and the conditions of life in general, has reached a state of development which renders the physiology of past ages scarcely worthy of the name. The microscope has not been in our possession as an instrument of practical utility for fifty years, yet it has given us, it may almost be said, a new sense, and I will not merely say has extended pathology into new regions, but has made pathology a new science; functional or unsubstantial diseases are flitting before the microscope like ghosts at sunrise; nervous diseases, the most evasive, are becoming tangible; insanity is no longer a disease of the mind, but of the brain.

Yet still we cannot affirm that diseases require no further elucidation, or suppose that every remedy has been discovered, or that we even know the real use and properties of many we already possess. There are many opprobria of medicine which must be cleared away before we can indulge in self-satisfaction at our skill. Witness those scourges of humanity, cholera, hydrophobia, zymotic diseases, &c., before which we are still utterly powerless: are we indulging in vain hopes if we look forward with confidence to the day when the discovery of specific remedies will have deprived these scourges of their terrible sting and baneful power? It is at least worthy of our most strenuous efforts to labour for the realisation of such noble aspirations. When we look at the valuable therapeutic agents which have been introduced into medicine as the result of theoretical considerations deduced from physiological experimentation on the lower animals within the last few years, as compared with the results of thousands of years of mere empiricism, we have every reason to feel satisfied with the progress that has been made. The great group of the anæsthetics, one of the greatest boons to suffering humanity, and the conditions of their safe administration owe their chief origin to physiological experimentation on the lower animals; the hydrate of chloral, one of our most valuable and much-used remedies, owes its introduction entirely to this method; the nitrate of amyl, almost a specific for one of the most intense forms of suffering to which man is liable, was deduced from theoretical considerations and physiological experiment; and besides these new additions to our resources, the knowledge we have acquired from physiological experiment regarding the exact action of many drugs already in our possession has enabled us to extend their use, calculate with exactitude their effects, and prescribe them rationally; while the great facts of physiological antagonism have enabled us to counteract with the most effectual success many of what in former times were universally fatal poisons. Triumphs such as these may well encourage us to proceed; they not only justify, but if we have the best interests of humanity at heart, render imperative continued research of the same kind in the future. Yet, as if medical men were the most inhumane class living, there has been an outcry against them by a certain class of people, mostly women, of the class which furnishes the most advanced champions of women's rights, against what they are pleased to term the inhumanity and cruelty of physiological experimentation on the lower animals. It is not my intention standing here to make any apology for vivisection, or to reply to the numerous attacks recently made on its advocates and prosecutors. We may rest content with the approval of those who are capable of appreciating its real bearings, and the magnitude of the interests it involves. Judging from the style of objections advanced against it in the public press and elsewhere, I should despair of convincing its opponents by any arguments I might advance of its morality and necessity when practised with skill and without any unnecessary curiosity. "But on the other hand, we who are regarded as offenders have strong reason to feel aggrieved at the practice of those who, professing to have such delicate sensibilities, gratify their prurient propensities by prying into what was never intended for their eyes or ears, and which they have shown themselves incapable of understanding, though eminently capable of misrepresenting those who may be actuated by as high principles of humanity as they who would constitute themselves its guardians." It has been asserted by some as a reason for opposing physiological research that vivisection has never resulted in any practical good, or been of the slightest service in advancing the interests of medical science. Those who make such assertions proclaim aloud to the world the most valid reasons for paying no further attention to any opinions they may think fit to express on the subject, and in opposing this line of research ought in consistency to refuse to accept the advantages of the enlightened medical practice which can be proved to be the direct result of that which they so much condemn. It is well for themselves that they are compelled to participate in benefits which in justice they are not entitled to.

Clinical Records.

CASES IN PRACTICE.

Reported by John W. Martin, M.D.,
Assistant-Surgeon, Mayfield Factory Dispensary, Portlaw, &c.

Case XVII.—*Dulness over both Lungs, especially over the* *lateral and posterior surface of left—Tubular Respiration—Bronchophony—Pungent Heat of Skin—Area of Heart-dulness enlarged—First Sound weakened—Friction Murmur — Frémissement — Tenderness over the Region of the Heart—Dyspnœa—Attack commenced with Rigors, Headache, Nausea, Vomiting, and general febrile disturbance—Treatment—Recovery.*

THE following notes were taken Sunday, May 15th, 1875, when I was asked to visit H. K., æt. 50, wife of a factory operative. The history of her case is as follows :—

On Monday, May 10, whilst engaged in washing, and exposed to variations of temperature caused by her standing over the steam from the washing-tub and then going down to the river-side to draw water, she was attacked with rigors, headache, nausea, vomiting, and severe pain in the back and down the legs. Skin hot and dry, followed by fits of profuse perspiration ; dyspnœa ; short hard cough, unattended by expectoration ; general malaise. She went to bed, but neglected seeking advice or further treatment. Next day, Tuesday, the acute symptoms had passed off, the cough, dyspnœa, and pain in the back alone remaining. Applied a poor man's plaster to her back herself, and paid no further attention to the attack until 9 p.m., May 16th, when I was first asked to visit her. About 5 p.m., whilst sitting at her open door, she was again attacked with very severe rigors, vertigo, nausea, vomiting, headache, and violent pain in the region of the heart. At the time of my seeing her I found her in bed, decubitus dorsal, countenance anxious and drawn-looking ; nostrils widely distended and playing freely. Respirations 50 per minute, very shallow, and performed entirely by the voluntary muscles. Skin dry, hot, and *very pungent* to the touch. Much troubled with a short, hard, racking cough, attended with a little white mucous expectoration, untinged with blood. Tongue was clean ; bowels regular ; she passed large quantities of clear healthy-looking urine, free from deposit. For a long time previous to present illness she had been subject to frequent attacks of vertigo, dyspnœa, and palpitation. She had also been subject to repeated attacks of slight colds. Never had rheumatic fever that she can remember ; was not anæmic. Dulness generally diffused over the whole surface of the chest, but especially over the lateral and posterior surfaces of the left lung, and most marked at the inferior angle of the scapula at that side. There was no difference in the volume of either side as compared with the opposite. No flattening or bulging of the intercostal spaces, and but little difference in the extent of the respiratory movements ; the right moving with slightly greater freedom than the left. The extent and distribution of dulness was not altered by change of position on the part of the patient. Everywhere respiration very harsh and tubular, and accompanied by dry sibilant râles ; respiratory murmur scarcely to be detected, in the seat of most marked dulness. Voice sounds increased in distinctness, bronchophonous in the right and anterior portions of left lung, pectoriloquous in the axillary and scapular regions of the latter. The area of heart dulness greatly enlarged, its diameter measuring five inches in the vertical direction from the lower border of the third rib, and four and a-half inches in the horizontal, from the right margin of the sternum, at the articulation of the fifth rib, over under the left breast. Heart's impulse of fair strength, apex beat seen in the usual position, its impact accompanied by strong *frémissement*. First sound very indistinct, muffled, and distant ; the second fairly marked ; but both sounds much masked by a loud to-and-fro friction murmur, heard over the whole area of the heart's surface. This murmur was most marked towards the base, at a level corresponding with the third intercostal spaces ; it extended upwards as far as the second intercostal space, but was not propagated along the arch of the aorta into the carotids. It was heard very loud and distinct on placing the stethoscope over the region between the spine and internal border of scapula, on a level with the third and fourth dorsal vertebræ. I injected half a grain of morphia in solution, hypodermically, into the left arm. Applied a blister four by four over the heart, and ordered—

℞ Aquæ acetat. amm., ℥i.
Vin. ipecach., ʒij.
Tr. aconiti., ʒi.
Syrupi, ℥i.
Aquæ ad ℥viij. M.

Two tablespoonsful to be taken every fourth hour.

May 17th.—Skin cool and moist ; free from pain in the region of the heart ; got relief about an hour after the morphia injection, application of the blister, and the taking of the first dose of the medicine the preceding evening. She slept well during the night, perspiring profusely. Pulse, 84 ; respiration, 28, fuller and less laboured than before ; temperature, 98·4°, normal. Felt no pain in the head, nausea, or inclination to vomit. Heart's action not so strong ; impulse weakened ; first sound increased in distinctness ; area of dulness unaltered ; friction murmur softer, but otherwise unchanged. Treatment continued.

May 18th.—Improved. Dulness diminished over the anterior surface of the chest. Vertical measurement of heart-dulness decreased by one inch. Friction murmur very soft, and of a light brushing to-and-fro character. First sound weaker, and more indistinct than on the preceding day. Second sound strongly accentuated. Both sounds heard best over the base of the heart. Dulness very strongly marked over the dorsal surface of the chest over both lungs, especially at their bases, the left more decidedly so than the right. Loud sibilant râles were heard throughout the affected portions of lung. A few pleuritic friction sounds were heard here and there over the dorsal surface of the chest. Both râles and friction sounds were loudest and most abundant at the base of each lung. All over the dorsal surface of the chest the voice sounds had greatly increased in distinctness of enunciation. Altered the treatment to—

℞ Pot. iodidi, ℈ij.
Vin. ipecach., ʒij.
Tr. aconiti, ʒi.
Potass. bicarb., ʒij.
Liq. amm. acetatis, ℥i.
Syrupi, ℥ss.
Aquæ ad ℥viij. M.

Two tablespoonsful to be taken three times a day.

Directed portions of the chest to be well rubbed with an ointment containing croton oil and tartar emetic, until the characteristic crop of pustules

May 19th.—Suffered a relapse, with a return of all the severe symptoms connected with the heart and lungs. Felt a very violent pain in the region of the former, and a dull heavy oppressive one in the latter, especially in the scapular regions. She took a very large dose of her medicine, more than double the usual quantity, at the onset of these symptoms, in the hope of gaining relief. Soon afterwards she experienced a great tendency to syncope, and sufferrd much from the sense of nausea and desire to vomit ; these symptoms, together with dryness of the fauces and violent thirst, I believe to have been due in the greater part to the aconite and ipecacuanha contained in the mixture, but not altogether so.

Respirations 60, short, and very shallow. Pulse 96, weak and compressible. Temperature 98°, the observation being most carefully made. The low pulse and temperature were, I think, undoubtedly due to the depressant action of the aconite. Heart-dulness much increased in area, measuring five by six inches from the upper border of the third rib on the left side and from the right margin of the sternum over towards the left breast. First sound of the heart very faint and indistinct at the apex ; both sounds heard at the base. The friction murmur already described was much increased in intensity. The dulness in the chest, the tubular respiration, and the increased distinctness in the enunciation of the voice sounds, were all more pronounced. Loud sibilant râles were audible everywhere over the dorsal regions of the chest. The sputa were still slight, white, and frothy.

The face was very much flushed, she suffered from severe pain in the head, the bowels were confined for several days, and her tongue was coated with fur.

I applied a blister five by five over the heart, and ordered—

℞ Pulv. jalapæ co., gr. iv.;
Pulv. scammonii, gr. iv.;
Calomelanos, gr. ij. M.

Powder to be taken at night.

May 20th.—Blister was left on for eight hours, and rose well, discharging on being let a very large quantity of serum. Her bowels were well moved. Felt herself much improved. The pain about the heart and in the chest almost gone. Tongue clean and moist. Heart sounds improved; murmur much diminished in intensity. Respiration 20. Pulse 95. Temperature 97°. Directed her mixture to be continued, and continued the use of the counter-irritant ointment to the dorsal surface of the chest.

May 23rd.—Greatly improved. Pain gone from region of the heart; dulness diminished by one-half; murmur soft, but still very decided; impulse of the heart improved in strength; chest symptoms improved; the dulness, however, tubular respiration, and distinct voice sounds remaining. Pulse, temperature, and respiration normal. Tongue clean, appetite good, bowels regular. Skin cool and healthy.

Changed her medicine.

℞ Potass. iodidi, ʒi.;
Tr. aconiti, ʒi.;
Tr. cinchonæ, ℥iss.;
Sp. chloroformi } āā ʒij.;
Sp. amm. aromat. }
Infusi cinchonæ ad ℥viij. ℳ.

Two tablespoonsful to be taken three times a day.

May 28th.—Continued improvement, in the sense of general good health, and a return of her strength. No minute examination of the chest made. Quite able to resume her household duties. Medicine repeated and directed her attendance to be continued at dispensary.

I have no further notes of this case, as the patient never presented herself at dispensary as directed. I have seen her frequently passing in the street; she always replies to my inquiries by stating that she feels quite strong and well, and in the enjoyment of good health. She has certainly improved wonderfully in outward appearance. I suggest for consideration in connection with the foregoing case the following points:—

1st. Was not the the attack one of an acute character supervening upon pre-existing chronic affection of the heart and lungs?

2nd. To what was the increased area of heart dulness due.

(a) Pericarditis with effusion?

(b) Obstruction to the blood current in the consolidated lungs, and consequent distension of the right chamber of the heart, in a possibly weak, dilatable state of that organ?

(c) A combination of both effusion and congestion?

3rd. Was the fall in temperature that took place upon the 17th of May due to the action of the mixture prescribed, or was it a natural subsidence?

4th. What was the value of the accentuation of the second sound of the heart as a symptom?

The favourable result of treatment makes the case one of some interest, and therefore worthy of record.

Mr. Cowper-Temple's Bill for removing the disabilities of women to practise came on for the second reading in the House of Commons last week. After considerable discussion the Government gave assurances that at the earliest opportunity they intended carrying into effect the opinions of the General Medical Council on the subject, and the mover on this understanding withdrew his Bill.

WEDNESDAY, JULY 12, 1876.

THE CONJOINT SCHEME FOR IRELAND.

The reiterated recommendation from the General Medical Council in favour of the establishment of a Conjoint Examination for Ireland, and the prospect of a final settlement of the arrangements for a co-operation between the licensing bodies in England have stimulated the leading Irish medical authorities to a renewal of the negotiations which were brought to a precipitate termination three years ago, by an *émeute* amongst the grinders and teachers of Dublin. It will be recollected that the basis of a conjoint scheme had been agreed upon by the University of Dublin, the College of Physicians, the Apothecaries' Hall, and the Council of the College of Surgeons, and that that scheme, so far as it went, had been accepted and tacitly approved by the Fellows of the College of Surgeons. Until the consideration of the curriculum was forced upon the Conference Committee, and until it became obvious to all the world that the redundant lectures and fees required by the Irish College of Surgeons for its diploma must be curtailed to meet the feeling of the public and the competition of other licensing bodies, the negotiations went on tolerably smoothly and a harmonious understanding existed between the Irish co-operating bodies. The moment it became known however, that a clipping of fees was in prospect, the grinders and lecturers flew to arms, and by a unanimous *coup* (carried into effect by means of a resolution of the College of Surgeons and by a subsequent election of its Council) effectually broke up the negotiations and squelched the scheme. The three years which have since lapsed have lent strength to the movement in favour of conjoint examinations, and the conviction has become overwhelming that the selfish interests of institutions or of individuals cannot much longer be permitted to stand in the way of the reforms which every one admits to be inevitable. The University of Dublin has taken the initiative, and appointed Drs. Apjohn and Stokes, and the Revs. Drs. Haughton and Hart to co-operate with the representatives of the Irish Colleges of Physicians and Surgeons in the discussion of the subject. The College of Physicians have appointed the President, Dr. Gordon; the Vice-President, Dr. Hayden; the representative on Medical Council, Dr. Aquilla Smith; and the Registrar, Dr. Finny; and the College of Surgeons have appointed the President (Dr. Kidd), the Vice-President (Dr. Robert MacDonnell), Dr. Macnamara, and Mr. Walshe to meet the other representatives, and to report any understanding which may be arrived at. Should any conclusive arrangement be arrived at, it will necessarily include only the three principal licensing bodies. The Apothecaries' Company have not been invited to join in the negotiations, their pretensions to grant medical licences having greatly impeded former deliberations, and their corporation having been since then practically superseded by the Irish Pharmaceutical Society. The Queen's University has not been taken into council on the matter, because its interests and system are known to be directly incompatible with any reform and its administrative senate hostile to any improvement. The College of Physicians will, without doubt, in spite of the antagonism of Sir Dominic Corrigan and one or two others amongst the Fellows, join heartily in the consideration of the question, and we therefore anticipate a valuable result from the reopening of the question by Trinity College.

It is quite clear that the interests of the Irish grinders and lecturers, the Queen's University and the Scotch colleges, must give way sooner or later before the growing outcry against the medico-educational systems of the United Kingdom. The Government has given a significant hint that its intervention by Act of Parliament is quite possible. On the 9th of March, 1876, Lord Sandon, the Vice-President of the Privy Council, in his place in the House of Commons, said: "If satisfactory (conjoint examination) arrangements are concluded in England, I cannot but hope that they will lead to a like result in the other parts of the United Kingdom. In this state of the case I cannot give any opinion as to what may be the views hereafter of her Majesty's Government as to the expediency or necessity of proposing legislative measures to promote or hasten the general adoption of the Conjoint Scheme." This enunciation unmistakably declares the feeling of the Government that co-operation between the licensing bodies is desirable, and that if the bodies refuse to co-operate, it will be necessary for Parliament to compel them. By a majority of fifteen to six, the Medical Council, at its last meeting, approved and endorsed this view in the following resolution adopted on the 2nd of June:—"That this Council express their regret that up to this time, and after so long a delay, no scheme for an examining board for England, Scotland, or Ireland has yet been put in operation. The Council further desire urgently to press this matter of conjoint examinations upon the bodies whose duty it is to arrange and supervise the medical examinations in the several divisions of the kingdom." This resolution was supported by the representatives of the Crown, and, with the exception of Dr. Aquilla Smith, of all the universities and corporations in England and Ireland. It was resisted by the representative of the Queen's University and the Scotch colleges, whose opposition savours too strongly of trade interests to be worth anything as an expression of professional opinion. The question has now to be decided whether the Irish system of medical teaching is willing to be reformed, or elects to adhere to the old system until disestablishment and disendowment invades its preserves. If, in the next session of Parliament, Government shall have reason to know that voluntary amendment is impossible, it is likely that the Medical Council will not content itself with the further reiteration of its opinion nor the Government with hopes for the future.

◆

THE PHYSICAL PSYCHOLOGY OF CRIMINALS.

II.

In a previous article we drew attention to a somewhat remarkable address which Professor Moriz Benedikt, of Vienna, has recently delivered on the "Physical Psychology of Criminals," a translation of which is to be found in the current number of the *Journal of Psychological Medicine*. The space at our disposal only allowed us to give an analysis of that address; but the subject is invested with so much interest, both to scientific men and to the general public, that we may be excused for passing a few remarks upon it.

Although materialistic philosophers may now and then push their speculations too far, no unprejudiced person can, when reflecting upon the relationship between mind and matter, come to any other conclusion than that all human inclinations, impulses, and actions—all our emotions and passions—depend more upon the physical organisation and state of the brain than is generally supposed. We have no intention, even if we had the opportunity, of going deeply into this subject, otherwise we should be entering upon the old and fruitless controversy respecting the nature of free-will, human responsibility, and similar abstruse questions; but, nevertheless, we cannot deny that our cerebral constitution exercises a wonderful control over all our thoughts and actions—emotional, moral, and intellectual. It is true that one of the most recent writers on psychology, the eminent physiologist, Dr. Carpenter, is of opinion that will and consciousness are not functions of the brain, but in some way independent of it. But this belief is scarcely consistent with his general admission "that the operations of the mind are in a great degree determined by the natural conditions with which they are so intimately connected," and we doubt whether his views will be shared by other psychologists. We only have to look around us to see every day examples of various manifestations of moral and intellectual aberrations and weaknesses, which all the effects of education, all the force of example, all the pressure of threats and punishment, and all the influence of persuasion, utterly fail to remove. And the consciousness of being under the influence of some peculiar stamp or character of cerebral constitution—a character which seems to cast such a spell over our actions—is often felt more acutely, and often more deeply lamented by the individual under its control than by his relatives and friends. He has ambition to contrive what he has not energy to carry out; passions which he cannot govern, impulses and propensities which he tries in vain to resist, desires which death alone can quench—and withal he feels there is a something over which reason has no control, and before which even his will appears to bow down. Up to the present day that philosophy which traces all abnormal mental manifestations to a purely physical source has, by the great bulk of mankind been only allowed in the case of insanity and certain well marked diseases of the brain. But there was a time when the physical origin of insanity was scarcely admitted, when that more delicate part of our cerebral organization which administers to our mental and moral faculties was thought to be exempt from physical changes, when the maniac was thrust from society, not so much from a feeling of self-preservation, as from the idea that he was suffering from a purely physical or mental derangement, by which he forfeited the sympathy and attention usually accorded to all other maladies, and when, consequently, those who stood in most need of pity and protection, got the least, and were often treated more like malefactors than invalids suffering from a curable disease. And the time may come when, on the same principle which has done so much for the treatment of the insane, a truer appreciation of the nature and constitution of man, and a more enlightened humanity will induce us to side with the learned Vienna Professor in limiting the domain of human responsibility "incomparably more than is the case in positive legislation," in regarding the impulse of criminal or immoral natures in the light of natural laws, in entertaining the opinion that a deficient cerebral organization lies at the foundation of the immoral propensities and acts of criminals, and finally in sanctioning some alteration in our penal code, so as to place the criminal either in such a position as will permanently cure him of his evil propensities, or, if incurable, will, without resorting to capital punishment, debar him from ever again outraging the interests of society. But when Professor Benedikt asks us to believe that the abnormal organisation or constitution of the brains of criminals is of so gross and permanent a nature as to be recognised after death, we must certainly hesitate to go with him any farther. And our hesitation is the more justiable when he further asserts that this deficient cerebral organisation is attended by a corresponding alteration in the shape of the skull, and that this alteration is so visible as to enable us to announce during life-time the probability of existence of cerebral abnormities. In the first place, we are not satisfied with the data from which the above inferences have been drawn. It is, indeed remarkable, that the examination of four criminal's brains should have revealed one after the other such cerebral abnormities as Professor Benedikt describes, but before any satisfactory conclusion could be arrived at on the subject, a much larger number of examinations would have to be made, and the results compared with those obtained from an examination of an equally large number of brains furnished from the lower but non-criminal classes of society. And then the inferences drawn from an examination of the skulls of the 365 murderers in the Illanda prison are open to serious objections: The conformation of the craniums in the majority of these prisoners were, according to the Professor's observations, very remarkable; but it is not stated that careful examination was made of a large number of crania taken from that class of the community to which murderers usually belong. We have only the assertion that "the highest degree of occipital brachycephalia in normal persons—namely, outside the prison—is very rare, and the medium degree appears in very few." In such an investigation much would depend, as we have just hinted, upon the class of individuals among which it was conducted. For amongst the poorer inhabitants of large cities it is very probable that the defective physique and mental training which has been handed down from one generation to another would be found to be often acompanied by a less normal and symmetrical shape of the head than that which obtains among the more elevated and more highly educated classes of society. Then, again, as there was no opportunity of examining the brains of those 365 murderers, we cannot say whether, in one single instance, these supposed characteristic forms of skulls were accompanied by a corresponding variation in the conformation of the brain itself. It was just in this respect that the old phrenology most egregiously broke down. It was found—and we may here remark that the skulls of criminals were favourite illustrations with the old phrenologists—that protuberances or flattenings in the cranium were far from being invariably attended with a corresponding hollowing or prominence of the internal surface of the skull, and still less with a corresponding alteration in the shape of the brain beneath it. In the case of the criminals at Ilkander, Professor Benedikt and his friend were particularly struck with the want of prominence of the external occipital protuberance, and with the flatness of the occiput. This fact, however, even if verified by further observation, can have no significance apart from a corresponding deficiency in the development of the cerebellum and posterior lobe of the cerebrum. But not only has this cerebral deficiency not been made out, but the probability is that a careful investigation would fail to discover any such association. Professor Retzius, of Stockholm, has adduced the best anatomical evidence to show that the size of the cerebellum in those races of mankind among whom the greatest difference in the occipital projection obtains (such as the prognathous negroes and the pyramidal-skulled Asiatics) bears no relation to the degree of projection of the occiput, for the plane of this organ being somewhat oblique in the elliptical skull is horizontal in the prognathous, and nearly vertical in the pyramidal, while the size and anatomical relations of the organ are not in the least degree affected by this difference in its position. Now, what is true with respect to races in which there are such marked differences in the respective conformation of their occipital bones may be also true with respect to individuals, and the same remarks that have been made with regard to the cerebellum also hold good when applied to the posterior portion of the cerebrum.

◆

Notes on Current Topics.

Death from Chloroform.

On Wednesday last Mr. Norton was about to remove a fibrous tumour from the palate of a robust and healthy man, about forty-five years of age, in the operating theatre of St. Mary's Hospital. The patient was advised not to take chloroform, as the use of an anæsthetic would be inconvenient during the operation, and the risk would be increased by the blood passing into the larynx. The man, however, refused to have the operation performed without an anæsthetic, and as ether was not available in consequence of the rapidity with which its effect passes off, chloroform was administered by the gentleman attached to the hospital in the capacity of chloroformist. Before the patient was sufficiently under the influence of the drug for the operation to be commenced respiration suddenly ceased. Every known means of restoring animation were employed, but without success.

The Surrey Coroners.

The Surrey magistrates have recently had before them at the Sessions House an application from the Finance Committee for an increase to be made to the salaries of the coroners. It was proposed that the salary of Mr. Carter be raised from £1,170 to £1,442 per annum. During each of the past five years Mr. Carter had held 830 inquests, as compared with 673 at the last average. One of the magistrates wanted to know whether the district could not be divided, as it was impossible for one man to hold 830 inquests and properly to perform the duties. The Chairman (Mr. Penrhyn) said the Court had no power to divide the district. The office of coroner had been under the consideration of the Government, and Parliament would deal with the subject. The increase in the salary was allowed.

Eight Guardians committed for Refusal to carry out the Vaccination Act.

The Local Government Board having obtained a rule *nisi* for an attachment against the eight Keighley guardians who object to vaccination, summonses were served on them to appear in London. On leaving Leeds they were cheered by a large and noisy crowd of anti-vaccinators, who attempted a kind of demonstration.

The Solicitor-General applied to the judges of the Queen's Bench Division to make a rule absolute that had been granted against eight of the members of the Keighley Board of Guardians, who from time to time had refused to put in force the Vaccination Act. A mandamus was issued, upon which they passed a resolution to put the Act in force, and returned the writ that they had obeyed. Subsequently they rescinded that resolution, and another writ had to be issued, and as they declined to obey it the present rule called upon them to show cause why they should not be committed to prison for contempt. The defendants, in reply, said they entertained conscientious convictions against the Act, and declined to carry it out. The Lord Chief Justice said it was their duty to obey the law, and of this court to enforce it. If they objected to the Vaccination Act they should use means to get it repealed. The Court therefore ordered them to be committed for contempt, and it would be for the Crown to have it carried into execution.

Croup and Diphtheria.

The committee appointed by the Royal Medico-Chirurgical Society to consider this question, have issued a circular to the Fellows and others defining the terms croup and diphtheria, and requesting them to embody the results of their observations and experience in the form of replies to a number of questions appended.

"1. Diphtheria is a contagious specific disease, which is accompanied by the formation of false membrane in the pharynx, air-passages, and elsewhere.

2. Croup is a disease accompanied by the formation of false membranes (mainly in the larynx and trachea), the origin of which is in question. No case is to be spoken of as an example of croup in which false membranes were not observed either during life or after death."

"1. Is your field of observation situated in an urban or a rural district, or partially in both? 2. What is the nature of the locality as to climate, soil, elevation, proximity to the sea, or to a river; or as to the drainage or overcrowding of any part of your district? 3. Have any of these conditions appeared to you to exercise an influence on the prevalence of either form of disease? 4. At what seasons of the year does either form chiefly prevail? Do they prevail simultaneously, either sporadically or epidemically; or may epidemics of the one be distinguished from epidemics of the other? 5. In connection with what other diseases do they prevail; either with influenza or bronchitis, on the one hand, or with angina tonsillaris, or other forms of sore-throat, measles and scarlatina, or other specific disease, on the other hand? 6. Have you observed cases of croup setting in with catarrhal symptoms, unattended by difficulty of deglutition, or by deposit of false membrane on the fauces, to be associated with albumen in the urine or followed by paralysis? 7. Have you seen in the same family, at the same time, cases of croup in one member and of diphtheria in another; and have you any evidence to show that membranous croup is contagious, and capable by its contagion of producing diphtheria? 8. Taking the pathological fact of false membrane limited, or chiefly limited, to the larynx and trachea, what evidence can you adduce as to its origin, on the one hand, in the specific poison of diphtheria, and, on the other, in a definite exposure to cold, or any other cause of ordinary inflammation? 9. If you believe the two diseases to be identical in nature, on what reasons do you chiefly rely in forming your opinion? 10. If you have any hospital experience, or experience derived from a large school, will you be pleased to give the Society the benefit of it?"

Meeting of the British Medical Association at Sheffield.

The meeting will be held on Tuesday, August 1st, and three following days.

Dr. Sievking will deliver the Address in Medicine; Mr. Favell (Sheffield) in Surgery; Dr. Carpenter (Croydon) in Public Medicine.

There will be be a *Soirée* in the Weston Park Museum on the Wednesday, Public Dinner on the Thursday, and a Promenade Concert in the Albert Hall on the Friday.

The following is the programme of Excursions:—

Wednesday, August 2nd.

3 P.M. Messrs. Cammell and Co. will roll a large Armour-Plate, and invite the Association to witness it, and afterwards inspect their famous works.

Thursday, August 3rd.

11 A.M. Thomas Firth and Sons will forge a large Gun, and afterwards show other objects of interest.

Friday, August 4th.

I. Excursion to Wortley by road. Lord Wharncliffe invites 100 members of the British Medical Association to lunch, and to inspect the Collieries, &c.

II. Excursion to Wentworth House; by invitation from Earl Fitzwilliam.

Saturday, August 5th.

I. Excursion to Chatsworth and Haddon Hall, Derbyshire; by rail over the moors, sixteen miles. Invitation from the Duke of Devonshire for 100 to lunch at Chatsworth at 1 P.M. Mrs. Wrench's Garden Party at Haddon Hall (by permission of the Duke of Rutland), from 4 to 6

II. Excursion by rail to Matlock and its neighbourhood. Dinner at New Bath Hotel.

III. Excursion by rail to Buxton, through some of the finest scenery in Derbyshire. Invitation for limited number to lunch from medical men at Buxton. Inspection of the Mineral Baths, Bath Charity Hospital, &c.

Daily, in Sheffield.

From 2 to 5 P.M. Joseph Rogers and Sons invite inspection of their famous Cutlery works.

James Dixon and Sons invite inspection of their Electro-Plate works.

Royal College of Surgeons of England.

ON Thursday last the election of the Members of Council took place. Mr. Holden, Professor Humphry, and Mr. Simon were re-elected. Of the new candidates, Mr. Wheelhouse polled 116 votes, Mr. Adams 64, and Mr. Hussey 35. Mr. Wheelhouse, of Leeds, was therefore declared the new member of the Council.

Non-compliance with the Vaccination Act.

A QUESTION was asked in the House of Commons by Sir Charles Forster in reference to proceedings taken by the Walsall Union on seven separate occasions, against a man for non-compliance with the Vaccination Act. Mr. Sclater-Booth said in reply, that it was an unfortunate matter, and that the Local Government Board had suggested that if an individual were convicted more than once, it was questionable whether repeated prosecutions would ensure the vaccination of the child, and therefore it became a matter for consideration whether it was advisable to prosecute more than a second time. At the present time the punishment for non-compliance with the Vaccination Act is interminable, so that ultimately every child is vaccinated, unless by chance it escapes the viligance of the authorities; but if the suggestion of the Local Government Board should be carried out there will be a definite alternative—either the child must be vaccinated or so much money must be paid, or a corresponding punishment by imprisonment must be endured. There are doubtless numbers who would willingly purchase a martyrdom at such an insignificant price, and the result would be that many children would escape vaccination, a matter to be regretted as much for the sake of the children as for those with whom they might come into contact, should small-pox present itself in the locality.

If, as suggested, that after the failure of two convictions, further prosecutions will not ensure vaccination, then it will be better to increase the punishment, or by police regulations to enforce the vaccination of the child, notwithstanding prohibition by its inhuman parent. It might be objectionable to resort to force—to trample upon "liberty of the subject;" but the liberty of the subject cannot be understood to mean freedom to injure another.

"Red Tickets" under the Irish Poor Law.—Important Decision.

A MOST important and valuable enunciation of the law has been obtained at the Monaghan Quarter Sessions last week, by which the Poor-law Guardian who issues a "red" or visiting ticket to a person who is not a fit subject for poor relief, is fixed with the liability to pay the doctor's fees when the ticket has been cancelled. Although the number of cases in which visiting tickets have been granted to persons quite capable of paying for medical attendance has been legion, the liability of the person who grants the ticket or of the person who receives it has never been hitherto put in question, it being understood that nobody could be made responsible to pay for services rendered in the discharge of public duty, no matter whether those services were or were not legally demanded. The chairman of the Monaghan Quarter Sessions has decided to the contrary, and has ruled that, though the recipient of the relief cannot be made to pay, he not being the person who ordered the doctor's attendance, the guardian who issues the ticket may be held responsible if it can be shown that the ticket was issued to an improper person. The action was taken by Dr. Woods, of Monaghan, against the defendant Crumley, a publican, who issued a red ticket to the wife of a schoolmaster who, admittedly, was earning £75 a-year, and had other means. Out of five tickets issued by the defendant three were cancelled by the committee, and he admitted that he issued tickets to "every one," and "could not go round and find out who was poor and who wasn't." The Poor-law Guardian has been ordered to pay the doctor, and this decision, if placed beyond dispute, used with judgment and not over-strained, ought to be potent towards putting a stop to the gross abuses of the poor-law which prevails in a majority of districts in Ireland. It must, however, be borne in mind that, as far as the present decision goes, no proceeding can be instituted for recovery of fees until the ticket has been cancelled by the committee, and there will be, undoubtedly, much hesitation on their part in cancelling the ticket wherever it was understood that by so doing they lay open their brother committee-man to an action at law.

It will be for further debate whether the cancelling of the ticket is a necessary preliminary to the legal proceedings.

Rabies Successfully Treated by Woorara.

THE *Veterinary Journal* for July states that Offenberg, in his recent inaugural dissertation at the Berlin Hospital, gives the case of a girl, twenty-four years of age, who had been bitten eighty days before by a dog supposed to be rabid. Injections of morphine and the inhalation of chloroform having been used without benefit, seven injections of woorara, amounting in all to three grains, were given in the course of five and a-half hours. First the muscles became steadier, then the convulsive seizures less frequent, the dread of water and the pholophobia disappeared, and the voice improved. Some symptoms of paralysis now appeared, which reached their maximum the following day. On the second day there was a slight relapse of the symptoms of rabies, which was checked by an injection of a little less than half a grain of the woorara. The patient recovered slowly, a certain degree of weakness and sluggishness, and especially weakness of sight, remaining at the end of two months. There was inflammation, but no suppuration, at the points of injection.

Memorial to the late Dr. E. A. Parkes, F.R.C.P., F.R.S.

A PUBLIC meeting in aid of the memorial fund will (by permission of the Council) be held at University College, Gower Street, on Tuesday, July 18th, at 3 p.m., Sir William Jenner, Bart., K.C.B, F.R.S., D.C.L., &c., in the chair. W. R. Gowers, 50 Queen Anne Street, W., and G. V. Poore, 30 Wimpole Street, W., are appointed hon. Secretaries.

A general committee has been formed composed of his Grace the Duke of Westminster, K.G., the Right Hon. the Earl of Derby, the Right Hon. the Earl Granville, K.G., the Right Hon. Lord Aberdare, the Right Hon. Lord Belper, the Right Hon. Gathorne Hardy, M.P., the Right Hon. Robert Lowe, M.P., Sir William Jenner, Bart., K.C.B., F.R.S., Sir James Paget, Bart., P.R.C.S., Sir W. Gull, Bart., F.R.S., Sir Henry Thompson, Professor Acland, F.R.S., G. Aitchison, Esq., Professor Aitken, F.R.S., R. Quain, Esq., F.R.S., Professor Russell Reynolds, F.R.S., Professor Sharpey, F.R.S., Dr. Sieveking, Surgeon-Major De Chaumont, Professor Erichsen, F.R.S., and about fifty other leading members of the profession.

The attention which hygiene is now receiving in this country is due in no small degree to the labours of Dr. Parkes, who was the first to deliver a systematic course of lectures on the subject, and it is hoped that a sufficient sum may be collected to establish at University College a museum and laboratory of hygiene similar to those now existing at the Army Medical School, Netley.

There is at present no museum of hygiene or sanitary science in London, and it is felt that the establishment of such a museum would prove a great boon, not only to the members of the medical profession, but also to engineers, architects, and others, who are interested in sanitary progress.

Increase of Small-pox in London.

IT appears that fifty patients suffering from small-pox have been received at the Stockwell Hospital during the past fortnight, four have died, and seventy yet remain in the hospital.

The report of that hospital shows that the increase of the epidemic is somewhat alarming, forty-one cases have been admitted during the week. They come mostly from the South of London, and are unfortunately of a malignant type. The Homerton Hospital is to be at once opened.

The Contagious Diseases (Animals) Act, 1869.

THE Privy Council have appointed the following gentlemen to be inspectors for the purposes of the above-mentioned Act:—William Wilkinson Smart, M.R.C.V.S., James Thomas Handy, M.R.C.V.S., and Joseph Henry Irish, M.R.C.V.S. The following gentlemen have ceased to be inspectors of the Privy Council for the purposes of the above-mentioned Act:—Adolphe Harrison Thomas, M.R.C.V.S., and Neville Bruce, M.R.C.V.S.

Double Conviction of an Unqualified Practitioner.

AT the Chelmsford Petty Sessions, on the 16th ult., Mr J. J. Young, who has been practising at Chelmsford as a physician and surgeon since the commencement of the present year, was summoned at the instance of the Medical Defence Association, under the fortieth section of the Medical Act, 1858, for that on the 8th of January last, he did "unlawfully, wilfully, and falsely, pretend to be, or take or use the name or title of Doctor of Medicine, physician or surgeon." The case was conducted by Mr. Pridham, solicitor to the Association, who called witnesses to prove that on the above date, the defendant caused an advertisement to be published in the *Essex Newsman*, in which he described himself as a physician and surgeon. The defendant's solicitor contended that his client was what he described himself to be, although his name was not on the *Medical Register*. The Bench considered the charge proved; and, as it was shown that he had been previously convicted of a similar offence at Ipswich, a fine of £15, in addition to costs amounting to £5, was inflicted. The defendant pleaded for a mitigation of the penalty, on the ground that a summons from another court was hanging over his head under the Apothecaries' Act; but the magistrates stated that they had nothing to do with any other court, and refused to reduce the fine. The money was at once paid. On the following Monday, the same defendant was sued at the Chelmsford County Court, under the Apothecaries' Act, for illegal medical practice; and the full penalty of £20, exclusive of costs, was recovered. The above is stated by the *Student's Journal* to have been the first case in which the Medical Defence Association has been able to get sufficiently conclusive evidence to justify prosecution under the Medical Act of 1858.

The Irish Registrar-Generalship.

THE *Civilian* learns that the Lord Lieutenant of Ireland has appointed Dr. W. M. Burke "Assistant Registrar-General," and that he will shortly be promoted to the full office of Registrar-General—on the resignation of Mr. Donnelly, who has held that office since 1844, and whose declining health has rendered him, for some time past, unable to attend to his official duties. The office held by Dr. Burke, that of Medical Superintendent of Statistics, will not be filled up, the Government will thus save the salary of £700 per annum, attached to it, out of which ample compensation by way of increase of salary should be made to the Chief Clerk, Mr. Wilkie, for all the chance of further promotion in the department being for ever shut out from him. Dr. Burke's appointment will give the greatest satisfaction to the public, the medical profession, and the Civil Service generally. In Dr. Burke's case we are glad to find the fact exemplified, that faithful discharge of official duties is quite consistent with kind and generous treatment of subordinates. We believe for the future the Registrar-Generalship will be given to a member of the medical profession, as there will be no "medical superintendent" in the department.

We heartily endorse the opinion thus expressed by the *Civilian*. The MEDICAL PRESS announced Dr. Burke's promotion and the changes in the Irish Registration office more than a month ago.

The New Pharmacopœia.

The Executive Committee of the General Medical Council met last week, in order to carry out some of the resolutions remitted to them by the general body. One of these referred to a new edition of the Pharmacopœia, the last of which is nearly out of print, and it was decided to issue another with all possible speed. As there will be no additions or alterations (except clerical) it is expected the work will be out in October next.

Education at a Discount.

At the last meeting of the Executive Committee of the General Medical Council, it was decided to advertise the appointment of Registrar, vacant by the resignation of Dr. Hawkins—who has held the post since the formation of the Council—in the four leading medical journals, and one lay newspaper. It is well known that if employers of mechanical labour want good, honest workmen, they have to search very diligently indeed to find them. Mechanics and labourers of very doubtful reputation have no difficulty in finding employment, whilst the services of men of education and clerks are at a decided discount. We have heard of firms in the City and elsewhere getting applications by the hundred for the appointment of clerk at less than £100 a year, whilst in one instance over five hundred applied for a secretaryship at £250, including men of birth and education, half-pay officers, &c., with the highest testimonials and recommendations. The cause of this educational—we might almost say—degradation, is not far to seek, but into this it is not our province or intention to enter. Rather do we regretfully ask ourselves, what will the effect be when a *bonâ fide* advertisement appears in public print of an appointment worth £500 a year, and short office hours, and this be it understood not confined to medical men? To the nine hundred and ninety-nine unsuccessful applicants out of a thousand —there are sure to be as many—we offer our sympathies in advance. It is not a *bespoke* office; from the character and position of the gentlemen to whom is delegated the decision, we are confident that the best man, according to their judgment, will be selected. Let us charitably hope that, whoever he may be, he may occupy the position as long and honourably as his predecessor, and not give occasion to put another thousand educated men in a flutter of expectation of £500 a year for some years to come.

A Dangerous House.

One of those so-called "Medical Halls," of which there are so many in London, belonging mostly to quack doctors, gained for itself such a notoriety last week as will not improbably lead to its extinction. From the evidence given at the Marlborough Street Police Court on Saturday it appears that Mrs. Snoxell, the wife of a blindmaker, the Thursday evening previously sent out a lad with directions to procure 1oz. sal volatile from the nearest chemist. The lad, by mistake, went to this "Medical Hall," and was served with something, upon his request to be supplied with sal volatile. When the lad returned with the stuff, complainant administered so many drops to her son, who had complained of severe headache. He was immediately taken with a kind of convulsion, almost suffocated, and remained all night in such an alarming state, that, although attended by a medical man, it was doubtful whether serious results would not take place. She therefore asked the magistrate for a summons against the person who sold the lad the pernicious article in place of the comparatively innocuous drug he asked for. The summoning officer said the place was notorious. There were outstanding complaints against it. An officer reported that the lad had identified the person who had served him, that person being more like a labourer than a medical assistant. If we mistake not, this is the house which was kept by the notorious quack Bell, and so fearlessly exposed by Mr. Courtenay in his book, "Revelations of Quacks and Quackery." That such a place is dangerous to the public and a scandal to our laws no one will attempt to deny. Whatever the ultimate results of the magisterial inquiry now being instituted, the individual concerned, whoever he may be, may congratulate himself that he is not in the dock upon the capital charge, the life of the child being at one time in imminent danger from the poison which had been sold.

Prosecution under the Medical Act.

A man named Walton, of Shadwell, was summoned at the instance of the East London Medical Protection Association for having falsely pretended to be a doctor of medicine and surgeon. A detective said that he took a note of certain inscriptions on the doors and windows. On the front door, and on a board inside the window was painted "Dr. Walton." The defendant was not mentioned in the "Medical Register" for the present year. The defendant said his name was Thomas Spiller, but he represented a firm named "Dr. Walton." He contended there was no proof that he had called himself a qualified medical practitioner. The magistrate fined him £20 and costs.

Adulteration of Whisky with Sulphuric Acid.

A Greenock publican has been fined £10 for selling whisky adulterated with sulphuric acid to such an extent as to be, in the opinion of the local analyst, injurious to health; the report was confirmed by an analysis made at Somerset House. It was stated by the Procurator Fiscal that many complaints had recently been made regarding the quality of the whisky supplied to sailors and marines at the shops in Greenock, and that lately several of the crew of H.M.S. *Aurora* had been taken seriously ill from the effects of drinking the adulterated liquor.

Lunatic Asylums in Scotland.

As an instance of how the public "jump at conclusions" upon insufficient data was shown a second time in one sitting of the House of Commons last week. We have referred to Mr. Dillwyn's motion on the Lunacy Laws elsewhere. Another member had got hold of a notion which he put forward as a fact in the stereotyped fashion. His (Mr. Ramsay's) attention had been called to the evidence given by the proprietor of a private lunatic asylum in Musselburgh, when he was examined as a witness in an action in the Court of Session, who stated that business men had been put into his asylum to avoid the Bankruptcy Court, and ministers to avoid trial by their presbyteries.

The Lord Advocate, replying, said the statements in question had been thoroughly investigated by the Commissioners of Lunacy in Scotland, and the witness, Mr. Chalmers, gave them two cases in support of his evidence. It was found that in each of those cases the certificates had been given by medical practitioners of high reputation, and that one of the men had been detained a year, while the other was still under restraint. The Commissioners reported that they had never had the smallest reason to suspect the good faith of any medical man who granted certificates in cases of insanity, and in their opinion the evidence given by Mr. Chalmers could only be accounted for by the imperfect acquaintance of a man untrained in medicine with the manifold aspects in which the malady presents itself.

The Lunacy Laws.

Doubtless Mr. Dillwyn was actuated with a becoming spirit when he brought forward his motion in the House of Commons on Friday last. We believe it is the desire of every member of that august assembly to introduce only those matters which concern the public good; how often they fail for lack of proof of the grievances they seek to remedy, from a knowledge of one side only of a question, or the riding of a hobby with which other members have no sympathy, is notorious.

In submitting his motion—"That, in the opinion of this house, those laws do not afford sufficient safeguards against illegal incarceration, and the maltreatment of lunatic patients"—the honourable member very forcibly illustrated the axiom that "a little knowledge is a dangerous thing." He said he had been led to inquire into the working of the lunacy laws, and he was satisfied that these laws were loosely administered with regard to the treatment of lunatics generally, and that the laws themselves were inherently bad, as they did not afford proper protection to lunatics, but rather gave facilities for their improper detention. He believed that the enormous increase in the number of lunatics which had taken place throughout the country was attributable to extreme laxity in the administration of the laws. Pauper lunatics and paid lunatics were on a very different footing. A pauper lunatic could not be incarcerated except in a public asylum on the warrant of a public authority, but a paid lunatic could be committed to a private asylum merely on the certificate of two doctors. Now he thought that in the case of the committal of all lunatics there should be the intervention of some public authority. The next point which he wished to impress upon the house was the desirability of doing away with private asylums altogether, for he considered it perfectly monstrous that the keeper should be the man who had the power of deciding whether a person under his charge should be released or not, when he had a positive interest in detaining him. The state of the law was so bad that he (Mr. Dillwyn) had felt bound to take up the question, and had at first thought of moving for the appointment of a select committee to investigate the matter, but he had not had the opportunity of so doing, and had come to the conclusion that the best course which he could pursue was to bring the subject before the house in the way he had now done. He did not suppose that it would be possible to get rid of private institutions at once, but trusted that their extinction would not be long delayed. That the house did not entertain Mr. Dillwyn's views was shown by the numbers present being insufficient to form a quorum. The Lunacy Laws are sufficient for all purposes, notwithstanding the argument expressed to the contrary. As to the abolition of private asylums, the public are not at all likely to submit to this so long as they are under the supervision of competent visitors, as at present.

Vivisection Cruelties.

An evening contemporary, the *Globe*, directs our attention to one of the most reprehensible acts of cruelty it is possible to conceive, and which out-Herods experimental physiology, but which neither county magistrates nor jurymen could be found to condemn. It appears that a practice exists in the north of England to which the Society for the Prevention of Cruelty to Animals might direct their attention.

"Two men were recently charged with malicioully wounding three sheep, the property of a farmer named Murray. About the facts of the case there was a little dispute. The evidence conclusively proved that the prisoners had cut away the feet to such an extent that the unfortunate animals could not walk. Mr. Murray stated that one of them was so badly wounded that he believed it would have bled to death if left to itself. For the defence it was contended — and the evidence unquestionably supported this view of the subject — that it is a common custom in Cumberland to pare sheep's feet to prevent trespassing. In the case in question, the three animals were caught on land belonging to Mr. Murray's neighbour, Major Thompson, and the two men, who were in the employ of the latter gentleman, thought themselves justified in applying the local remedy for straying proclivities. On the first occasion of the matter coming on for trial the jury could not agree, and were dismissed without delivering a verdict. The case was retried on the 26th ult. at Carlisle, and, after taking exhaustive evidence about the local practice in such matters, the jury acquitted both prisoners. Cumberland law would thus seem to affirm the eccentric principle that it is legal to maim animals that are found straying on land not belonging to their masters. This is the legal aspect of the decision, and a very curious one it is. From a humanitarian point of view, there appears even more reason for calling in question the verdict of the twelve wise men of Carlisle. A horse and cattle doctor, possessing 36 years' experience, gave the following testimony as to the nature of the injuries inflicted on the three sheep. 'Two of them had their feet cut to the centre; the sole being completely cut away. Matter was oozing from the feet of both. The third had its hind feet cut in a similar manner to the others. The whole lot were so badly cut that they were not likely to recover for several weeks.' As no attempt was made to rebut this evidence, it may be taken for granted that the facts were as stated. The only defence consisted in a plea of justification by custom, coupled with the high characters for humanity that were given to both prisoners. This latter is almost invariably a feature in cases of alleged cruelty to animals, and the evidence on that head may therefore be taken for what it is worth. The point really maintained in this connection by the jury's finding is, that to pare away sheep's feet to the core and then leave the victims bleeding to death on the ground does not constitute cruelty to animals in Cumberland."

Insolatio.

A case of sunstroke terminating fatally has occurred at Brighton. A young man, a carrier by trade, whilst waiting in a van exposed to the sun, fell down insensible under its influence and shortly afterwards died.

Small-pox is somewhat less prevalent in Manchester and Salford, though still epidemic; there were 18 deaths last week.

At Taunton, Frederick Culliford, a herbalist, of Crewkerne, was sentenced to 12 months' imprisonment for witchcraft.

Addenbrooke's Hospital, Cambridge, is to be immediately enlarged by the addition of a new wing at a cost of £3000.

Liverpool seems to be on the verge of a severe small-pox visitation. The deaths from this disease suddenly rose last week to 17, and it is feared fatal cases are on the increase.

At the Manchester Police Court, a milk dealer, in Welcomb Street, Hulme, was fined for keeping his house open for the sale of milk whilst a member of his family was suffering from small-pox.

An action for libel is being tried before the Court of Common Pleas in London between the surgeon (plaintiff) and captain (defendant) of one of the large ships belonging to the Union Company.

The annual general meeting of the Medico-Psychological Association of England will be held at the Royal College of Physicians, Pall Mall, London, under the presidency of William H. Parsey, M.D., on Friday, July 28th, 1876, at 11 a.m.

In the House of Commons on Thursday last, in reply to Mr. O'Leary, Mr. Hardy stated that the claims of no senior surgeon-major of the army who possessed proper qualifications would be passed over in the selections for promotion to the rank of deputy surgeon-general, but regard would be had in granting promotion to the cases of men who had displayed surpassing ability.

On Thursday last, Mr. Hardy stated, in reply to Dr. Playfair, in the House of Commons, that he had no doubt the promised warrant for militia surgeons would be issued during the present session in time to receive the consideration of Parliament. It had been approved by the Treasury, and only awaited the signature of her Majesty.

Surgeon-Major W. Collis, of the 3rd Buffs, has presented a very interesting collection of weapons and projectiles, from the late seat of war in the Malay Peninsula, to the Museum at Netley. The weapons consist of Malay spears, swords, kreases, and knives of various forms. All the weapons and knives were taken in action at Kota Lama, on the right bank of the Perak river, on the 4th January last.

A large deputation from the Poor-law and medical officers of his late district, in the north of Ireland, waited on Mr. O'Brien, Local Government Inspector, at his residence in Dublin, and presented him on behalf of their body with a farewell address, expressive of the universal regret felt at his removal to another sphere of duty, accompanied by several valuable pieces of plate and works of art, in commemoration of the event.

Mr. E. G. Alabone, a surgeon, residing at Earlswood House, Richmond Road, Hackney, committed suicide last week with prussic acid. Deceased was a man of very intemperate habits, and in consequence of his conduct his daughter had on the evening of the 3rd inst. threatened to remain no longer in the house, and went to the gate to call in a policeman. The deceased passed her, and when he had gone a short distance he fell and expired in a few minutes. The jury returned the verdict "Suicide while of unsound mind."

Several cows belonging to three farmers living in the parish of Glounstane, near Mallow, were lately attacked nearly simultaneously with "charbon," or "malignant pustule," and before anything could be done to relieve them four of them died. Some of the intestines of one of the animals that died were cut up and given to ducks, which lived a very short time after eating them, so the disease must have been a very poisonous one. The police had the carcases buried, as the disease is highly contagious and fatal.

A return made by Mr. Simon states that the following reports are in preparation with a view to their being laid before Parliament:—Two reports by Dr. Klein on the intimate morbid changes occurring in scarlatina and in the enteric fever in swine; a further report by Dr. Sanderson on the process of fever, particularly with reference to the constitution of the pyrogenetic ferment in septic infection; a further report by Dr. Creighton on anatomical studies with reference to cancer; and a further report by Dr. Thudichum on the chemical constitution of the brain.

Correspondence.

ENGLISH SURGERY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—An article appeared in your paper of June 14th under the heading of "English Surgery," relative to the death of Captain Leader, which article I was more than surprised to read, inaemuch as almost the whole facts of the case were entirely mis-stated and grossly incorrect. Consequently the public have got a most erroneous idea of the true facts of the case, which are simply these. About the end of April last Captain Leader was in Dublin, where he consulted Mr. Butcher and Mr. Porter for a disease of a surgical nature, which he suffered from for some years. Both of those surgeons told him he had but a short time to live, and they would not do anything for him. On hearing this, which required that great amount of moral courage and wonderful pluck which Captain Leader possessed for any man to have been able to bear up against, he determined on going over to London, and having further advice, a determination I strongly recommended him to carry out at once, believing and telling him an operation could and would be performed which, if it did not cure him altogether ("and which there was a good chance of its doing "), it would certainly have prolonged his life very much.

In the commencement of May he consulted Sir Henry Thompson, Sir James Paget, and Mr. Erichsen, who were unanimous in advising an operation, and on the 11th of May Sir Henry Thompson operated and removed the whole of the local disease completely and perfectly, and not, as stated in your report, "only a small part of it." The wound was healing so rapidly, and the patient doing so well, that he took food abundantly, and walked into an adjoining room on the tenth day after the operation, having all the appearance of a rapid recovery. So far from dying "within a day or two" of the operation, it was not until the date just named that he showed symptoms, at first slight, afterwards increasing, of pyæmia, or blood-poisoning, a condition which all medical men know may and does occasionally occur after any operation, whatever its nature, and which is wholly unconnected with the character of the disease, or the special operation undertaken for its removal. This complaint carried off Captain Leader on the 23rd day after the operation in question.

I shall feel obliged by your inserting this in the next issue of your paper, as I think it only fair to the English surgeons concerned in the case.

I remain, Sir, your obedient servant.
R. Radley Leader, M.D.
Keale House, 26th June, 1876.

[The statement to which our correspondent refers was corrected in the succeeding issue of the Medical Press and Circular (June 21st) by the following paragraph:—

"In our last issue the circumstances of a case were narrated in which an operation had been performed by London surgeons upon a patient whose case had been declared hopeless and entirely unsuitable by the highest surgical authorities in Ireland, the result being speedy death to the patient. The case thus referred to was that of the Rev. Mr. Longfield, of the county Cork, and though intended merely as an illustration of the same method of practice which is stated to have been pursued in the more recent case of Captain Leader, it was inadvertently made to appear as a statement of the circumstances attending the latter gentleman's death. The facts as stated by us last week are accurately true as regards the Rev. Mr. Longfield. In Captain Leader's case the disease is stated to have been cancer of the testis, extending up the cord, and capable of being felt in that position and up in the iliac regions, by the surgeons and the patient himself. He was seen, after attendance by the local practitioner, first by Mr. Butcher, and afterwards by Mr. Porter, the two highest surgical authorities in Ireland, who concurred in opinion as to the hopeless extent of the disease, and strongly advised against any operation. Nevertheless the patient was operated on in London, and with a fatal result. We are ourselves cognisant of more than one case in which patients declared by a concurrence of the best ophthalmic opinions in Ireland to be hopelessly blind, were operated on in London, apparently without hesitation, and certainly without the least benefit. As we have said, these cases, and others of similar import, have created in Irish surgical circles an unpleasant feeling."

We believe that the facts are correctly stated in the forgoing extract. There was, it appears, a difference of opinion between the Irish and English surgeons, the view expressed by the former being fully justified by the fatal result of the case. We are not called upon to decide in such a dispute, and have only to record the fact that the operation which was condemned by the Irish surgeons was performed in London with fatal result.—Ed. M. P. & C.]

◆

THE VIVISECTION BILL.

The largest and most influential deputation of the profession we ever remember to have seen gathered togeth for this or any other purpose was attempted to b crammed into the smallest and most inconvenient room in the Home Office on Monday afternoon, to urge upon the attention of Government, through the Home Secretary, Mr. Cross, the necessity for further alterations and amendments in the Vivisection Bill, now called "The Cruelty to Animals Bill." We observed among those present Mr. Torrens, M.P., Mr. Mitchell Henry, M.P., Sir William Jenner, Mr. Simon, Dr. Quain, in short, the heads of the profession in town and country, to the number of two or three hundred. The deputation was introduced by Mr. Hart, who read letters of apology from Sir James Paget, Sir Thomas Watson, and others, and he then called upon Mr. Simon to address a few remarks to the right hon. gentleman. In the course of a very animated and telling speech, he denounced the action of the Government in giving way to a sentimental and fanatical clamour, which took us back to the dark ages and the persecution of a Versalius and a Galileo. He showed that the Bill went far beyond the requirements of humanity, and was crude and unsatisfactory in its details; that it would make it penal for a man of science "to scratch the tail of a tadpole under the microscope, whilst it permitted all kinds of cruelties to be perpetrated for sport and for the gratification of the appetite." The question of morality, he contended, was settled by the common sense of mankind, which never hesitates to sacrifice animal life to the preservation of human life and health. The question of utility must be settled by scientific investigators, who were every jot as humane and considerate as members of the House of Lords, who had already given their sanction to a Bill which degraded the medical profession and brought them to a level with "ticket-of-leave men." Sir William Jenner followed with a few well chosen words of censure and condemnation of those who uttered the most reckless falsehoods against the profession, and who for the most part were guilty, not simply of an error of judgment, but of a moral fault—a violation of decency and Christian charity. Dr. Wilks took up the question from a practical point of view, showing the great good conferred upon medicine by the labours of practical physiologists; and Mr. Seeley, of Aylesbury, illustrated this by his own labours with regard to vaccination and small-pox. The Home Secretary's reply was chiefly occupied by a defence of his colleagues, and the action of the Government in this matter, who, he contended, was actuated by the best of motives and a desire to bring a disagreeable agitation to a close.

◆

DEPUTATION TO THE HOME SECRETARY ON THE VIVISECTION QUESTION.

A deputation of the members of the British Medical Association was received by the Secretary of State on Monday last. The room in which the deputation was received together with the passages around were crowded. Mr. Hart introduced the deputation, stating that the petition presented was signed by 2000 members of the medical profession. Nearly all the leading London physicians and surgeons were present, and letters were referred to from Sir James Paget and Sir William Gull stating their concurrence with the views of the deputation.

Mr. Simon said undoubtedly vivisection was carried on in the present day, but by not more than twenty men, who devoted their time to science; but they exercised that practice deliberately and with a sense of responsibility, and, he might add, of pain also—with a feeling that vivisection could not be avoided. Man is not responsible for the law of nature, the struggle for existence; the prosperity of man and of animals also was dependent upon such sacrifices; the slaughter of animals taken for food is one of the prices paid for the progress of man and also even of beasts. He admitted that physiologists in France and Germany attached less importance to the method of vivisection than was attached to that practice in England; there they doubtless sacrificed a great deal of animal life, but they did not stop short at animals, they sacrificed themselves too. They were not less reckless of their own lives than of those of lower animals. Mr. Simon then paid a compliment to Dr. Klein, showing that he had been picked out as a scapegoat, adding that there was no one more strict than Dr. Klein in principles, and that all English physiologists were willing to bear the onus equally with him. As regards the Bill, every one would feel respect for the motives with which it was introduced. Scientific men recognised a moral obligation upon themselves not to cause unnecessary sufferings, but when moral obligations were converted into police obligations; when men of science were to be treated as ticket-of-leave men, the profession could not but feel injured and aggrieved. One would be willing to accept a law that every man should account for the suffering he inflicted, but he considered this Bill was due to a great deal of public feeling influenced by organised associations against a handful of scientific observers. In days gone by precisely the same organised arrangement was used against Vesalius, the anatomist. It might have been anticipated that the Government of the country would have sided with science against such agitators, but he had to regret that it was otherwise. He considered that the Bill was unnecessary. Surely the Home Office was not to be made responsible for every scratch that was made upon a tadpole's tail. He believed that if it were generally known what actually takes place in the laboratories where vivisection takes place no one but a Pharisee would have signed a memorial against it. Mr. Simon then referred to the recklessness with which animals were injured, tortured, and mutilated for the sake of gain and of sport, and yet all these miseries which animals were made to endure were not to be considered, whilst a dead set was to be made against about twenty scientific men—an outrage against the medical profession, and a national disgrace.

Sir Wm. Jenner said the right hon. gentleman who received the deputation had seen 10,000 times more cruelty inflicted than all scientific observers. He would refer to a well-known picture of Landseer's, the "Otter Hunt." If he wished to hold an otter fixed upon a spear-point whilst dogs should tear it limb from limb he might do so with impunity, but if, as Mr. Simon had said, he scratched a tadpole's tail as an experiment, he must obtain a licence from the Home Office. He might drown a puppy if he liked, but if he wished to know how long that drowning would take he must first obtain a licence. No law so utterly absurd could be accepted.

Dr. Wilks said that, as a teacher at a medical school, he could say that if that Bill became law his duties of the profession could not be carried out. He could not teach with any scientific method except by means of the results o experiments the works of physiologists. The Bill would affect not only the physiologist, but the whole working of the profession. Had this Act been passed some short time back the works of Herbert Spencer, Carpenter, and others would not have been written, and the world would have been in happy ignorance of facts now proved, and now the basis of medical science. Stronger feelings than professional called him there that day—they were those of patriotism. It was no *doctors'* question, it was a question affecting the whole nation. He had heard from many of his friends who were members of the House of Parliament that their tables were crowded with pamphlets full of the most scandalous libels and falsehoods in connection with this vivisection question. He could state that vivisection was practised only by the few, and it was absurd to suppose that experimentation was carried on by medical students. He considered that it would be sufficient to license vivisection under the Anatomy Act.

Mr. Ceely, of Aylesbury, referred to the experiments upon animals by which the relation of cow-pox to small-pox was discovered, and to experiments made upon sheep, by which it was proved that a malignant disease was not capable of modification, and therefore must be got rid of by stamping out. It was Lord Palmerston's special request that these experiments should be carried out on a greater scale, but Mr. Ceely considered the question settled, and therefore refused to sacrifice the animals unnecessarily.

The Home Secretary was glad to receive the views of so large a body of influential men. Reference had been made to external agitation, but the deputation must not conclude that the Government had acted upon that agitation. There were two Bills before Parliament last year—one by Dr. Lyon Playfair, a Bill which would certainly have been stamped with carrying the same mark of disgrace to the profession as it was stated the Government Bill was stamped with; yet no one could say that Dr. Playfair was not acquainted with professional views. The Government, not influenced by any agitation, had appointed a commission and framed their Bill in accordance with the report of that commission. (No, no, no.)

Mr. Hart said the memorial presented went fully into the question.

The Home Secretary repeated that practically the Bill met with the approval of the members of the Commission.—(No, no)—but that literally the deputation required that the matter should be left alone.

Mr. Hart said the memorial suggested alterations.

The Home Secretary continued that the session was flying past, that external sentiment and agitation would continued, and that it depended upon the line taken and the policy declared by the medical profession whether the Bill should fall through to another session and whether the present Bill should be allowed to pass—perhaps with some slight alterations.

MEMORIAL.

That the number of persons in Great Britain engaged in the pursuit of physiological and medical research by experiment on living animals is very small, in all, perhaps, not exceeding twenty.

That the results of such investigations in this country and abroad have been, and are likely to be, in the highest degree conducive to improvement in the knowledge and treatment of disease, and to the mitigation of the severest scourges which afflict mankind and the brute creation.

That the pain incidental to such investigation is largely annulled by the use of anæsthetics; that the sum of suffering connected with or caused by physiological experiment is so small as to be infinitesimal when compared with that which is, without any attempt at regulation or restriction, inflicted by farmers, farriers, trappers, hunters, fishermen, and others, for the purposes of trade, domestic convenience, or sport.

That notwithstanding the excited allegations to the contrary which were publicly made last year, and since widely disseminated, the comprehensive inquiry of the Royal Commission has failed to elicit evidence of even a single instance of want of humanity among the professors and teachers of the medical schools and universities of Great Britain; and speaking of those schools the commissioners are able unanimously to state that "the evidence shows conclusively that the sense of humanity in the students is not in fact impaired."

That the experience and knowledge of all the teachers in medical schools, and of those persons who have the most ample opportunities of knowing, entirely negatives the allegation that unpractised students are at all in the habit of performing, or do perform, painful experiments on animals. Such a practice among students is described by the Royal Commission as being at least "exceptional and abnormal"; it may, however, be more accurately asserted not to exist at all; further, the authority of the professors and the force of opinion among the students may be confidently relied on to prevent any such practice from arising.

That the medical profession are deeply penetrated with the sentiment of humanity, and the consciousness of the nature and evils of pain, and that all mitigation and prevention of suffering, whether of man or animal, has sprung from their researches, and is due to their daily labours.

That no abuse of physiological experiment has been shown to exist in this country, nor is there any reasonable ground for believing that it is likely to exist; but on the contrary, it may be safely assumed that professional opinion and authority will always suffice to prevent inhumanity to animals in this country as a thing repugnant and detestable to the feelings and convictions of the medical men of Great Britain.

That no special legislation whatever is called for in respect to any existing practice of experiment on animals in this country, nor is there any probability of its being required.

That the present Bill, intituled "An Act to amend the Law relating to Cruelty to Animals," is in fact a measure which, so far as it extends that law to other than domestic animals, makes the infliction of pain penal only when it is inflicted for the purposes of knowledge, and not under any other circumstances; that it casts a stigma, therefore, and imposes restrictions precisely upon that class of proceedings, and upon that class of persons, whose objects are most laudable, whose character is most trustworthy, and who inflict the very smallest proportion of pain when compared with the numerous classes of agriculturists, farriers, traders, trappers, and sportsmen, whose business involves the wholesale infliction of pain.

That the Royal Commission desired that any measure framed upon their report should aim at removing the feeling of suspicion which has been permitted to grow up against those who are devoted to the improvement of medicine and to the advancement of science, and that any such measure should be framed upon the model of the Anatomy Act, according to the suggestion of several of the most eminent witnesses.

That the present Bill goes far beyond the recommendations of the Commission, and the just inferences from the weight of evidence before them, inasmuch as

1. It treats the persons who have, upon due recommendation, received a "license," as permanent objects of suspicion, and requires of them that they shall (*a*) apply for and obtain from the Home Secretary for the Home Department special permits or certificates for every series of experiments calculated to produce pain; (*b*) that they shall submit to whatever regulations or restrictions the Secretary of State may append to such certificates; (*c*) that they shall furnish to the Home Secretary whatever reports he may require as to such experiments; (*d*) that they shall only perform such experiments in registered places which he shall approve; (*e*) that whenever it is necessary to perform an experiment on a cat or dog, a horse, ass, or mule, a further permission shall be obtained from the Secretary of State.

It is, moreover, to be remarked that the first four of these restrictions apply to the whole range of the animal kingdom, from the smallest tadpole or mollusc through the whole of the invertebrate as well as of vertebrate creatures.

This Committee therefore recommends that if any legislation should be thought necessary it should be general and not special in its scope, and should extend Martin's Act, with such amendment of its machinery as may be found necessary, to other than domestic animals, to which its operation is now limited, and that the present "Cruelty to Animals' Bill" be withdrawn.

If, notwithstanding the foregoing representations, the present Bill be further prosecuted, then the Committee recommend that the analogy of the Anatomy Act, which alone was approved by the eminent witnesses before the Commission, be followed, and that the Bill be amended.

I. By limiting its operation to the vertebrate kingdom of animals.

II. By omitting all the clauses which require special certificates in addition to licenses for performing painful operations; and further special certificates in respect to dogs, cats, &c.

III. By providing that a licensed person may register any convenient place for the purpose of experiment, and that such register shall be a confidential document, accessible only to the Secretary of State, and to such officers and persons as he may appoint for the purpose of carrying out the provisions of the Act.

IV. That a register of all experiments performed shall be kept by the licensed person, and that such register shall be at all suitable times open to the inspector appointed under the Act, but that no other reports or returns shall be required from persons licensed under this Act.

◆

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this.

"Jos·kers."—The specimens should be sent to the dissecting-room crier at the nearest Medical School. It is possible that some of them might be found useful to the students, but should they be of no value a very small trifle will be expected for the trouble entailed.

M.R.C.S.—Your communication will appear in an early issue.

THE USES OF JABORANDI.

To the Editor of "The Medical Press and Circular."

Dear Sir,—Have you or your subscribers any experience of the medicinal properties of the Brazilian remedy "Jaborandi?" If so, would you or they let me know in your next issue the dose, mode of preparation, and how produced? Rusticus.

[Jaborandi is a Brazilian plant belonging to the natural family Rutacere. The leaves are employed in medicine. They resemble in size and shape the leaves of the common laurel, but as met with in our commerce are of a yellowish colour. From these are prepared a powder, an infusion, a tincture, a wine, and a liquid extract. The dose for adults of the powder would be from ten to thirty grains; of the infusion, from half an ounce to two ounces; of the wine or tincture, from half a drachm to two drachms; and of the liquid extract, from ten to thirty minims. Its most marked effect is diaphoretic and sialogogue; it has been used in simple fevers with these objects in view, and in cases where a parched condition of the mouth has been a prominent symptom its sialogogue properties have afforded very sensible relief. In such cases, for obvious reasons, one of the fluid preparations should be preferred to the powder. The various preparations above enumerated should be procurable at any respectable pharmaceutical establishment.—Ed. *M. P. & C.*]

M.D., Wolverhampton.—Proofs have been forwarded.

THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.

PATRON:—H.R.H THE PRINCE OF WALES.

This Institution was founded in 1869, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develop the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £40 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote.

Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c, can be had at the office,

PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S.

&c. (KING'S COLL.), and Author of VIA MEDICA.

Has always upon his books a large number of desirable Investments and available Appointments for negociation.

The business of the Professional Agency is based upon the general principle, that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

COMPETENT ASSISTANTS provided without expense to principals. No Gentlemen recommended whose antecedents have not been inquired into.

LOCUM TENENS.—Dr. Langley has now organised a thoroughly reliable Staff of suitable Gentleman to take full Charge of any Practice which may require it in the absence of the principal, at fees from £2 12s. 6d. upwards, according to age, experience, qualifications, &c. One of these gentlemen can be despatched by an early train after receipt of telegram or letter stating duties and terms. Office fee 10s. 6d., payable by the principal.

A 148. WEST OF ENGLAND. A good class Practice, realising, on the average of the last 3 years, £948, and actual receipts last year, £1,024. The connection has been in the present hands for upwards of 20 years. Midwifery limited to £2 2s. and £3 3s. The residence is large and convenient, with stabling, coachhouse, garden, &c.; being the Vendor's freehold, it could be purchased or rented. 12 months' introduction would be given if desired. The district is well populated and pleasant. Opposition unimportant.

A 147. PARTNERSHIP suitable for a gentleman devoting himself to chest diseases is offered by a practitioner residing in a favourite health resort on the South Coast. The present Practice amounts only to about £500 a year, but is capable of great and immediate increase.

A 146. DEATH VACANCY. Receipts of late Incumbent upwards of £900 a year. The connection is suitable for a young gentleman of active habits, to whom the whole could be transferred. There is a comfortable house, containing 11 rooms, with lawn, kitchen-garden, stabling, &c. Rent, £40. The Practice is well cared for, and a complete introduction can be given. An arrangement can be made for the greater part of premium to be paid by instalments, and part may be dependent on receipts; but no gentleman need apply who cannot command £200 in present cash.

A 145. DEATH VACANCY. London Suburbs. Receipts, £600 a year. Appointments, £30. Midwifery, £1 1s. and upwards. House contains 7 rooms. Rent, £37. An efficient introduction can be given. Qualified Locum Tenens in charge. Terms, £150 down, and the remainder by instalments.

A 144. OPEN SURGERY at the West End. Receipts at the rate of £400 a year. House contains 8 rooms. Rent, £50. Unlimited scope for increase.

A 141. First-class PRACTICE near LONDON. Receipts, £1000 a year. Midwifery, from 2 to 10 guineas. Visits, 3s. 6d. to £1 1s. All appointments declined. The residence is beautifully situate, large and convenient, with garden, stabling, and extensive grounds. Rent, £120.

DR. LANGLEY'S QUARTERLY LIST (for JULY OF SELECTED PRACTICES AND PARTNERSHIPS FOR TRANSFER IS NOW READY. Post-free on Application.

IRISH POOR-LAW INTELLIGENCE.

THE IRISH MEDICAL ASSOCIATION AND THE DUBLIN CORPORATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The Council of the Irish Medical Association have recently had their attention directed to a petition presented to the House of Commons by the Corporation of Dublin in support of the "Coroner's (Dublin) Bill," and inasmuch as some of the statements contained in this petition are calculated to injure the reputation of the Irish Medical Association in the estimation of the public, I have been directed to request that you will kindly give publicity through your columns to the following remarks.

The Council do not think it necessary to enter upon a discussion as to the merits of the measure itself, further than to remark that the Council are of opinion that if the Bill should become law in its present form it will be prejudicial not only to the interests of the profession which the Council represents, but also to those of the public at large, and will be calculated to interfere with the due administration of justice in cases requiring the intervention of the coroner. The Council beg to direct attention to the following points:—

1. The Corporation of Dublin object to the office of coroner being confined to the legal, medical, and magisterial professions, and pray "that the selection of the most competent person should be left to the judgment and discretion of the Municipal Council." In the opinion of the Council of this Association a knowledge of medical jurisprudence is absolutely necessary for the efficient discharge of the duties of coroner, and this knowledge is only possessed by members of the medical and legal professions. The Council further believe that the public would not be satisfied that the selection of coroner should be confined to the present Corporation of Dublin without careful safeguards being provided as to the qualifications of the persons selected.

2. The Council protest in the strongest way against the slighting and insulting manner in which this long-established and well-known Association is referred to in the following paragraphs of the petition of the corporation:—

"Your petitioners have learned that a petition in reference to the "Coroner's (Dublin) Bill" has been presented to your honourable House from certain dispensary medical attendants and others in Ireland, styling themselves the "Irish Medical Association," in which reflections are indulged in upon the arrangements and practice in Dublin as to medical evidence at inquests.

"Your petitioners are in a position to declare the allegations in said petition to be in nearly every instance erroneous, and quite deficient in correct knowledge of the facts. The existing arrangements impugned by said petition have been made after mature consideration and experience by the presenting Grand Jury and affirmed by the Court of Queen's Bench. Dispensing medical attendants, in claiming that they themselves should be the persons called in to give medical evidence, cannot be expected to have weighed all the circumstances as fully and impartially as the Presenting Grand Jury and the Court of Queen's Bench have done."

The statement that "the existing arrangements impugned by the said petition have been made after mature consideration and experience by the Presenting Grand Jury," &c., is misleading, because in this instance the petitioners and the Presenting Grand Jury are the same persons; thus, to uninformed persons, the statement above referred to would imply that the practice of the corporation and of the city coroners is annually considered by another body separate from the corporation, and has been even framed by that body, whereas no such *separate* body as the Presenting Grand Jury really exists. The fiating by the Court of Queen's Bench merely means that the Court passes such presentments as are not traversed by rate-payers or others having a *locus standi* before the Court.

With reference to these reckless assertions, the Council beg to state that the Irish Medical Association has existed for upwards of half a century, and although its operations were interrupted by the great famine and distress in Ireland in 1847, yet it was completely reorganised, and has been in full and uninterrupted operation since the year 1853. It is not therefore a new or unknown association, as the Corporation, petition would seem to imply. The Council can scarcely understand how such an allegation has been made by the Corporation, as the present Lord Mayor is a member of the Association, and must be supposed to be fully acquainted with its aims and objects.

The statement that the Association consists of "dispensary medical attendants and others," is manifestly meant to imply that the Association is carried on solely for the benefit of the Poor-law medical officers of Ireland, and that the petition referred to is merely an attempt to obtain fees for those officers. This implication is without the slightet foundation in fact. The Association is composed of Irish physicians and surgeons, and now numbers over 550 members, including many of the most eminent practitioners in Ireland.

The Council of the Association, as representing men belonging to all classes of their profession, protest in the strongest manner against the insulting tone adopted by the Corporation towards many hundreds of the members of a learned profession, who have carefully and diligently served the public and the State for upwards of a quarter of a century. The confidence of the State in the services rendered by the Poor-law medical officers of Ireland has been proved by the fact that in every enactment where public medical duties have been required, those duties have invariably been confided to the Poor-law medical officers of Ireland. The Council are of opinion that a service trusted by the State and respected by the public should not be insulted with impunity by the Dublin Town Council.

3. The Council have to observe that although the Dublin Corporation allege that the statements put forward by this Association are "in nearly every instance erroneous," yet that body does not mention any particular error; therefore the Council do not consider the statement of the Corporation demands a detailed denial, but they beg emphatically to affirm that every statment put forward by the Association can be substantiated by facts well known to its members. The Council deeply regret that such a body as the Dublin Town Council should have thought it becoming to go out of its way publicly to insult the members of a learned profession who devote so much of their time and attention to the public welfare.

Your obedient servant,

ARCHIBALD HAMILTON JACOB, M.D., F.R.C.S.,
For Chairman of Council.

THE IRISH MEDICAL ASSOCIATION AND THE CORONERS BILL.

TO THE EDITOR OF THE IRISH TIMES.

SIR,—An editorial notice in one of your contemporaries of the letter which I addressed to you on behalf of the Irish Medical Association contains statements in reference to the administration of the Coroners' Courts in Dublin which demand a reply from me. My letter is devoted, not to the discussion of the existing system of medical testimony in Coroners' Courts in Dublin, but to the justification of the Association from the disingenuous and insulting statements contained in the Corporation petition; and my council will receive with gratification the repudiation of these statements by the Lord Mayor, and the implication, on the part of your contemporary, that the phraseology of the petition cannot be defended. As, however, the editorial remarks of that journal apply almost exclusively to the system of medical evidence in Dublin Coroners' Courts, against which the Association has complained, it is necessary that I should refer to this subject, to which I only alluded indirectly in my former letter.

The petition of the Association against the Coroners' Bill complained that—

1. There would, if it became law, be but one coroner for Dublin.

2. That at present "the testimony of the only competent medical witness" (*i.e.*, the medical practitioner who had seen the deceased person about the time of death, or who resided in the neighbourhood) is habitually excluded from the consideration of the jury.

3. That in defiance of the 28th Section of the Coroners' Act, 9th and 10th Vic., cap. 37, which provides for the payment of fees for evidence to a different practitioner in each case, an individual witness, who is not supposed to be an expert, is salaried by each coroner in Dublin to give all the evidence which juries may require.

The first objection to the Bill, that under its provisions there would be but one coroner for Dublin, the Association justifies by a reference to the annual returns of inquests which will be found at page 1,264 of "Thom's Directory for 1876," from which it appears that on an average of six years 270 inquests have been held each year. This number represents one such investigation each day of the working year; and as several of them frequently occur together, and many of them extend over several days, the Association considers that it will be impossible for a single coroner to comply with the requirements of justice by holding a speedy and exhaustive inquiry in each suspicious case. The appointment of a deputy has, in the opinion of the Association, no advantage, and many disadvantages, in comparison with the appointment of a second coroner, and we know of no instance in which a single coroner is entrusted with the investigation of causes of death in a population of nearly a quarter of a million of persons as proposed by the Bill.

The second objection of the Association to the present system is, that the testimony of the most competent medical witness (*i.e.*, the practitioner who had seen the deceased person about the time of death, or who resided in the immediate neighbourhood) is habitually excluded from the consideration of the jury.

In a letter addressed by the Association to the Irish Members of Parliament upon this subject, the following passage occurs: "When a death occurs which requires investigation it would seem reasonable and necessary that those persons who had the best knowledge of the cause of death should be called upon for their testimony. Of such witnesses the medical practitioner who saw the patient at the time of death, or immediately before or after it, is obviously the most valuable informant of the jury; for not only has he personal knowledge of the actual circumstances, but he possesses an expert knowledge of the cause of death, and has necessarily formed an opinion as to the relation of the symptoms to such cause."

Your contemporary gives, in the opening of its editorial statement, a point blank denial of this assertion, and declares: "That under the present system the medical man last in attendance is usually summoned and is paid his fee," but as later on it admits that the instances in which this is *not* done "are ninety per cent. of all cases," it seems almost unnecessary for the Association to repeat its assertion. However, to remove any ambiguity, I beg, on behalf of the Association, to deliberately reiterate their assertion that "in the city of Dublin the law is constantly evaded, and the coroners habitually make use of the latitude which the indefiniteness of the law affords them to employ their personal friends and relatives as medical witnesses. Notwithstanding the expressed intention of the Legislature, the medical testimony laid before the jury in a case of sudden death is seldom that of the practitioner who saw the deceased at his death, nor of the practitioner indicated by the law as "in actual practice at or near the place of death," nor (except in rare cases) of a medical jurist whose profession it is to investigate such subjects. On the contrary, a general medical practitioner is called upon to testify as to the cause of death, who perhaps resides some miles from the place; probably never saw or heard of the deceased until he sees the dead body; knows nothing of the place at which the death occurred, or of the persons who have been concerned in it; and, lastly, has no special qualification as an expert to decide upon such matters. I challenge the Dublin coroner to justify the statement of your contemporary that the medical man last in attendance is usually summoned, by stating in your columns the number of cases out of the 299 inquests held last year in which the medical man who saw the patient immediately before, at, or after death, was called as a witness and paid. Your contemporary confesses that in ninety per cent. of all cases this is not done, and gives as a reason that in these instances the cause of death is obvious—a statement which reference to statistics and experience of the system will show to be entirely erroneous. In 72 out of the 279 inquests held last year, the causes of death are set down as other than natural or accidental, and amongst them are classed 15 from intoxication, 8 suicides, and 44 "miscellaneous." The Association submits that in every one of these cases the opinion of an independent medical man, who had some knowledge of the circumstances, ought to have been laid before the jury; and, furthermore, believes that very many of the deaths set down as from natural causes and accident are so classed simply from ignorance of the real causes, and because the necessary medical evidence and post-mortem examination being dispensed with, the jury is insufficiently informed. It is needless to point out that if this belief be justified, there is great danger the crime may go unpunished, and that negligence which has resulted in a violent death may be frequently overlooked.

The Association, lastly, complains that in defiance of the Coroners Act, which provides for the summoning of a medical man "in actual practice at or near the place where such death has happened," and orders the payment of each such witness by a stated fee, the Dublin Coroner employs in almost all cases a medical man, his own relative, who is paid, not by fees, but by a yearly salary. It pleases the coroner to interpret the phrase "at or near the place" as signifying the place of residence of his relative anywhere within the city of Dublin, but the Association submits that it is a palpable contravention of the law so expressed to employ a practitioner resident close to Nelson's Pillar, to investigate a death occurring in Marrowbone Lane or Montpelier Hill, to the exclusion of the medical man who lives on the spot, who possibly attended the deceased before death, and who probably was called to his assistance at the moment of death. The facts which are above stated the Association is prepared to prove, and it is for the public to judge whether, after proof, the inferences contained in our petition are or are not justified, and whether the assertion of those opinions lays the Association open to the insults with which the Corporation has endeavoured to meet them.

I am, Sir, yours, &c.,

CHAIRMAN OF COUNCIL IRISH
MEDICAL ASSOCIATION.

P.S.—Your contemporary concludes its article by attributing an *animus* to me, and states that it "could tell more than would be pleasant in connection with this matter." As I have never, to my knowledge, seen either of the coroners or their medical advisers, and have never had the opportunity of earning an inquest fee in my life, and hope never to be in so unpleasant a position, I failed to comprehend the inuendo, and therefore invite your contemporary to disclose the nature of my personal motive, if it considers that aspect of the question relevant to the facts.

LEGAL INTELLIGENCE.

WILLIAM WOODS, M.D., *v.* WILLIAM CRUMLEY AND — M'GEOUGH.

IN this case two processes were issued, one against M'Geough for £5 for professional services rendered to his wife by the plaintiff; and the other for £5 against Mr. William Crumley, spirit-dealer, a *quondam* Poor-law guardian and dispensary committee-man for Monaghan. The plaintiff is dispensary medical officer for Monaghan, and M'Geough is a national schoolmaster in receipt of £60 or £70 a-year between salary and results fees. The action against Crumley was for £5 for that he, the defendant, in or about the month of November, 1875, being then a member of the Monaghan Dispensary Committee, and as such authorised by law to issue a ticket to the medical officer of said district, directing him to afford medicine and advice, and to attend any poor person resident in said district, did issue a ticket to the plaintiff, he being the medical officer to the said dispensary district, directing him to attend one Catherine M'Geough, who was not a poor person or entitled to relief, in consequence of which ticket and of defendant's requirement, the plaintiff sought to recover the amount named in the process.

Mr. Givan and Mr. Knight appeared for Dr. Woods, and Mr. Reilly and Mr. Ross defended the action.

Mr. Givan, in stating the case, said this case had been before the court at last Quarter Sessions, and then his worship was of opinion that they could hardly succeed against M'Geough, and it was struck out on the ground that the then defendant, M'Geough, was not the retainer, but the person who issued the ticket, and he refused to dismiss it, declaring that a fraud had been practised upon Dr. Woods. They now came before the court again in order to have the law decided by his worship, and that Dr. Woods might in future be protected against the fraudulent and vexatious issue of red tickets by members of the Dispensary Committee, who gave them sometimes without making proper inquiries, sometimes capriciously and vexatiously.

The Chairman said he would be delighted to give a decree against the party if he could show him that he would be justified in doing so; because it was a most improper proceeding on the part of a guardian to issue a ticket for a person who was not contemplated by the Act as being unable to pay.

Mr. Givan then read the words of the Act, 14 and 15 Vic., which enacts that members of Dispensary Committees have power to issue tickets addressed to the medical officer of the dispensary district, directing him to afford medicine and advice, or to attend in person on such sick person. Now, without going further into the duties imposed upon members of dispensary committees, of discriminating between parties who are entitled and parties who are not, it was clear from the general orders that "visiting tickets are to be given in cases of *necessity* only, and with all available information as to the nature of the case; and care should be taken to fill up the ticket and apprize the applicant accordingly, as the medical officer of each dispensary district is only bound to attend any *poor* person resident therein." The "age and occupation of the applicant should also be stated." Mr. Givan read from "Harrison on Wrongs," that any public officer, whether paid or unpaid, who, by any exercise of authority vested in him, shall injure an individual, an action will afterwards be, at the suit of such individual, against such person, holding such public office. It would be evident to the court that the dispensary officer was bound to attend to these tickets, to prevent himself being in continual hot water. On the other hand it would appear that persons aspiring to be Poor-law guardians and members of dispensary committees were bound to exercise due discrimination in the issue of red tickets; otherwise it would be in the power of dispensary committees or Poor-law guardians to throw upon the dispensary officer an amount of labour which no amount of salary would pay him for, and which it would be impossible for any human being to attend to. Mr. Givan then read authorities to show that Mr. Crumley was the person in this case, against whom an action, *ex delicto*, lay. He issued this ticket on the 4th November last. Dr. Woods visited her on that day once; on the 5th once, when she had a very bad confinement; on the 6th twice; on the 7th twice; on the 8th twice; on the 9th twice; and on the 10th, notwithstanding that he was of opinion that he would not be required to visit her before eight o'clock that morning, Mr. M'Geough came to his door and knocked him up at four o'clock in the morning, and demanded that he should come at once and see his wife. Dr. Woods knew perfectly well that the woman did not require him sooner than eight o'clock in the morning, and gave him a draught, and told him he would be out at his house at eight o'clock in the morning. M'Geough abused him roundly, and said if he did not go then and there, he would report him to the Local Government Board, and that he would go and employ another doctor. He went to Dr. Ross of this town, who went to Dr. Woods' patient, whom Dr. Woods had been visiting once every twelve hours for five days, without in any way consulting Dr. Woods for a moment——

Mr Ross—That is the whole case.

Chairman—When did Dr. Woods take any action before the Committee?

Mr. Givan—On the 10th he brought the matter before the committee, and had the ticket cancelled. And not only was that ticket cancelled, but two others issued by Mr. Crumley of a similar character were also cancelled. And even after he had been turned out from being a Poor-law guardian and a member of committee, he continued to issue red tickets requiring Dr. Woods to visit and attend upon patients, as we will prove to you. Mr. M'Geough was a schoolmaster, receiving a salary of £30 a-year; his wife also had £30, he believed, making £60. The results fees for the past year he understood was £15 in each school, making a total of £75. Mr. M'Geough was not burdened with a family. This was his first child; he was able to consult a medical man before and after his wife had received the services of Dr. Woods.

Mr. Reilly—That is not true.

Mr. Givan—If Dr. Ross was not paid he should not have gone. At all events Dr. Woods wants to prevent himself being harassed by persons who have no right to issue tickets for Poor-law relief, or who, having a right, exercise it in an unjust and vexatious spirit.

Dr. Wm. Woods examined by Mr. Givan.

Chairman—I assume there is no controversy as to the facts.

Mr. Reilly—This much may be admitted—that Dr. Woods attended from the 4th till the 10th.

Dr. Woods—On the 4th November, in the evening, I received a red ticket, signed by William Crumley, calling on me to attend M'Geough's wife in her confinement. His house is three-quarters of a mile from town. I went at once. She had not been confined when I saw her. It was a very difficult case. I had to perform an operation in order to save either her or her child.

Chairman—Was the operation successful? The operation was successful; she was delivered on the morning of the 5th, and both she and the child were saved. I visited her again on the 6th. On that day I went twice; twice on the 7th; twice on the 8th; twice on the 9th; it was necessary for me to see her twice every twenty-four hours, regularly, which I did. I saw her between seven and eight o'clock on the evening of the 9th; I had then visited her ten times, and it was not necessary that I should see her again before eight o'clock the following morning; I was called in the night by her husband, or at four o'clock in the morning. He said his wife was very ill—that she was suffering and shouting with pain from retention. I knew that could not be, because I had fully relieved her at eight o'clock the previous evening. But she was hysterical, and it was hysteria which caused her to shout. I prepared a composing draught and gave it to him and said I would be out at eight o'clock. He refused to carry the draught to her, and said if I did not go that moment he would report me to the Local Government Board, and he would go there and then and employ another doctor. I told him he was exceedingly impertinent; that his wife had been attended by me in a manner with which any lady would be perfectly satisfied, and that he might go and get whoever he liked. At eight o'clock in the morning I was at his house, and found that Dr. Ross had been there and passed a catheter, some hours before. I did not believe that any medical man would come in and take up a case of mine behind my back, and I turned and left the house. That day there was a meeting of the dispensary committee. It was the ordinary meeting. I attended it and got the ticket cancelled. There were two others of Mr. Crumley's tickets cancelled the same day.

To Mr. Reilly—I was giving the same attention to Mrs. M'Geough as if she were a private patient. I had three other patients at the same time—private patients—and I did not think it necessary to visit them oftener than once in the twenty-four hours.

Chairman—This was a critical case.

Witness—It was a very critical case. M'Geough lives in a cottage belonging to Mr. Breakey. M'Geough is a teacher. His wife is also a teacher of the female department of the school. The manager of the school told me she also is a teacher; and I heard that between M'Geough and his wife he is worth £75 a-year or more.

Cross-examined by Mr. Reilly—I had the ticket cancelled. Did you give notice to Mr. Crumley that you were about to have the ticket cancelled? I have nothing to do with giving Mr. Crumley, or any other member of the committee notice; but if I am not greatly mistaken, I think I asked Mr. Crumley to attend the meeting. Do you know of any notice being given to Mr. Crumley?

Chairman—Ah! sure, every member is assumed to attend, as a duty.

Cross-examination resumed—I attended Mrs. M'Geough in her confinement. I had never attended her before. This was her first confinement. There was a certain organic derangement on the 10th November. It was four o'clock a.m. when the man came in for me. I did not think it necessary to attend.

I believe you went to Dr. Ross that morning? I believe I did. And you gave him the length and weight of your tongue? I did.

Mr. Reilly—Now, Dr. Woods, on your oath, and before your God, is not this action a matter of spite between you and Dr. Ross? I am not influenced by a feeling of spite. I am anxious to stop the irregular and indiscriminate issue of these tickets.

Mr. Reilly—When was the ticket cancelled? At the meeting of the dispensary committe. How was that meeting convened? In the regular way, I believe.

Mr. Reilly—I will show you, sir, it was not a properly convened meeting, but a hole-and-corner one got up for a special purpose.

Mr. Reilly (to witness)—How long did you attend this woman? When I saw her, I attended her up to the night on which her husband called on me. I heard it as a fact that Dr. Ross had seen her before the confinement, and I believe it to be the case. I heard Dr. Ross performed an operation on the woman the morning he was out; but I would not have done it. The same operation had been performed at eight o'clock the evening before, and I would not have passed a catheter again at four the next morning.

But it was done, and she survived it? Oh, it is not a very fatal thing to do. Did you get any other tickets cancelled besides Mr. Crumley's? Yes; Mr. M'Bride's and Mr. James Ross's.

Mr. Reilly—"Still harping on my daughter."

Dr. Woods—I can't see what connection there is between Mr. Ross and Mr. Crumley.

Mr. Reilly—Mr. Crumley is Mr. Ross's tenant—(a laugh). Is it not spite to Dr. Ross that has caused you to bring this action? It is not. Was it spite towards Dr. Ross? I would have brought the action if Dr. Ross had been at Kamskatska. Did you speak to Dr. Ross? Yes, I had a conversation with him.

Mr. Reilly—You may go down.

Dr. Woods—Since Mr. Crumley became a guardian, the average of tickets issued has been increased by 300 a-year.

Bernard M'Geough, examined, said he presented a red ticket to Dr. Woods on the 4th of November last, and, in consequence, he attended my wife from the 4th till the 10th. I am teacher of a national school. The average attendance is under 50 pupils; my salary was then £30 a-year; my wife had £20; the results fees were £10; and the school fees £4 6s. 11d. How long are you married? More than a year. The school is a mixed school.

Chairman—What were the fees in the female school? They were examined in the month of August.

What was the amount, sir? What did your wife get? A third of £10.

That £10 was your own—what did she get? The school was examined in August, 1875. What were the fees? The average was 50 last year? Have you any money saved?

Chairman—Surely you don't mean to say that a man in receipt of such a salary as that is entitled to a relief ticket? Tell me, sir, what put it in your head to go to seek relief in this way?

Witness—I considered I was entitled to it.

Chairman—You wanted to save your pocket at the expense of the rates.

Witness—The reason was that the Monaghan Board of Guardians decided that the teachers should be paid something out of the rates, without any distinction.

Chairman—There can be no question on earth that in giving a dispensary ticket to a man like that, the defendant did an unjustifiable act.

Mr. Reilly—What rent do you pay for your house? Seven pounds.

Did any medical man attend your wife before her confinement?

Chairman—That does not bear on the question.

Mr. Reilly—I think it does. The gist of this action is because M'Geough called on Dr. Ross.

Dr. Woods—I deny that.

Chairman—Is that anything to me? Do I care anything for the jealousies of parties? The question for me is whether Dr. Woods is justified in bringing this action, and whether I can make Crumley liable for the act of giving that ticket.

Mr. Reilly—Very well: I will ask another question. What time did you come for Dr. Woods? I think it was between two and three o'clock, I don't recollect; but I think it was about that. I asked him to come and see my wife. He told me to go to h—, and that he would make me pay £1 a visit.

Dr. Woods—I deny that.

Mr. Forster Dunwoody examined—He said he was honorary secretary to the Dispensary Committee of Monaghan. The second Wednesday of each month was the day appointed for holding the monthly meeting. The ordinary meeting for November last was held on the 10th. Dr. Woods stated the facts in relation to the issue of this ticket, and his attendance on Mrs. M'Geough; he had four or five red tickets which he complained should not have been issued, and of the five, three were cancelled; M'Geough's was cancelled.

Was Mr. Crumley there? He never was at a meeting but one since his appointment.

Chairman—Mr. Crumley has now an opportunity of satisfying me, if he can, that the issuing of that ticket was a proper act. Let him show me that.

W. Crumley examined by Mr. Reilly—M'Geough applied to me for this ticket. I live in Monaghan—in the town. Did you consider M'Geough a proper person to obtain relief? Yes. Got no notice that a meeting was to be held to cancel the ticket, and no notice that it was cancelled.

Cross-examined by Mr. Givan—Was two years a Poor-law guardian; attended two meetings the first year, and one meeting the second. (Laughter.) Did Dr. Woods call on you about issuing those tickets? He did. He told you you should not give red tickets to your customers? No; but I said except I went round and saw them I could not know. They were issued in pursuance of your custom? I gave them to every one.

Mr. Givan—I see. A Poor-law guardianship to a publican is a step to good custom. Was it on the principle of his being a schoolmaster or a customer that you gave him the ticket? Neither. Did you not know that he was a schoolmaster? I did. And that his wife was a schoolmistress? Yes. He asked me for a ticket to the doctor to go to see his wife. I asked him what salary he had. He said about £30. Did you issue that ticket (produced) after you had ceased to be a guardian—"the ruling passion strong in death?" I never signed that. Did your wife? I suppose some one was instructed to sign it.

Mr. Givan—That is the way you prostituted the ticket-book of the Board.

The Chairman—after consulting Dr. Woods as to what he would have charged M'Geough, and being answered that he would only have charged three guineas—gave a decree for that amount. The case as against M'Geough he dismissed.

THE PHYSIOLOGICAL FUNCTION AND ANATOMY OF THE CRYSTALLINE LENS.

A LECTURE DELIVERED TO STUDENTS.

By ARCHIBALD HAMILTON JACOB, M.D. Dublin, F.R.C.S.,
Surgeon to the Dublin Eye and Ear Infirmary; formerly Ophthalmic and Aural Surgeon of the City of Dublin Hospital.

IN the convergence of the rays of light which proceeding from any given object impinge upon the cornea and are ultimately concentrated in an accurate image upon the baccillar layer of the retina, the chief portion of the work of convergence is done by the crystalline lens, and therefore aberrations either of the density or of the curvatures of that body are attended with much greater derangements of vision than any which alterations in the other refracting media, the cornea, the aqueous humour, or the vitreous body are capable of producing. The lens is placed in a depression formed for its reception on the anterior or truncated portion of the vitreous body and immediately behind the iris, the principal function of which is to confine the transmitted rays to the centre of the lens, and thus prevent the aberrations which in every homogeneous lens arises from the unequal refractive powers of its centre and its periphery.The crystalline body occupies, in fact, in the optical arrangement of the eye, the position of the inner lens in a photographic combination, or the eyepiece in a single opera-glass, the object-glass of such instruments being represented in the eye by the cornea, which forms a compound lens withthe aqueous chamber filled with its watery contents, the diaphragm which is interposed between the two lenses in any optical combination being represented in the eye by the iris.

The crystalline lens is biconvex, and of so thick proportionably to its diameter as to approach a globular shape. This it must necessarily be, because it has to concentrate parallel rays of light to an accurate focus at a very short distance behind itself. In some fishes, indeed, the lens is nearly quite spherical, because the cornea is nearly flat and the anterior chamber nearly obliterated, and, therefore, these media—forming, as it were, the object-glass of the eye—lend but little assistance to the lens towards the convergence of the rays, and, moreover, the whole eye being flatter from before backwards than the human eye, those rays require a greater convergence to bring them to an image on the retina. We are, of course, aware that the thicker a lens is the greater its refractive power, and the shorter its focal length, the greater are its aberrations or optical faults, and if, in the case of the crystalline lens, these aberrations were not corrected by the iris placed in front of it, by the sphericity of the retina behind it, and by the action of the ciliary muscle in changing its shape, the eye would be a very imperfect optical apparatus indeed, and we should never see the image of a distant object without blurred edges and fringes of colours round the margin.

In order that I may be understood in what I say as to the physiological functions of the lens, it is necessary that I shall recall to mind a few elementary facts as to the behaviour of rays of light when passed from a lighter through a denser lens shaped body — say, from air through a glass. Suppose a number of rays of light to be presented perpendicularly to an ordinary biconvex glass lens at different angles, as represented at Fig. 1, let us see what happens.

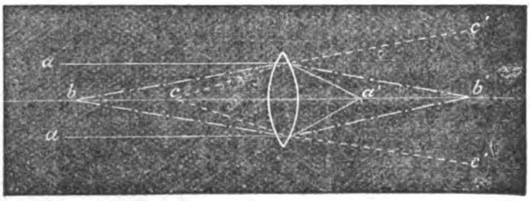

Fig. 1.

Those which strike the lens in a perpendicular direction and directly upon the axis will pass through without change of direction and onward to infinity. Those, however, which strike it anywhere else than upon its axis will be bent toward the axis, and if they be all bent to an equal extent, and if the amount of bending be sufficient, all the rays falling on the lens will all be gathered to a point at a certain spot called the focus. The bending or converging power of any biconvex lens is slightly less towards the centre than next the margin, but may, for the sake of illustration, be said to be always the same, no matter how the rays strike it, and the place where the rays are brought to a focus is situated, and whether the rays are brought to a focus at all depends altogether upon the spot whence the rays come before they strike the surface of the lens. Thus the rays given off by a distant object, though not mathematically parallel to each other, are practically so. They approach the lens from infinity, and are neither separating from each other in their transit nor closing together, and, if permitted to go on unrefracted, would still occupy the same relation to each other *ad infinitum*. If the biconvex lens be interposed in their line of progress it bends them together, those which strike the outer edge being bent most, those nearer the centre less, those passing through the centre not bent at all. They will thus be brought to a point which is called the principal focus of the lens or the focus for parallel rays. The path of such rays is represented by the unbroken lines *a*—*a* in the illustration.

But suppose these rays come from a short distance—for optical purposes anything under three feet is a short distance—but let us say, for illustration, twelve inches, they will proceed in a diverging direction, and if allowed to go on unimpeded would pass away from each other never to meet again. If the biconvex lens be now interposed the rays will be bent as before, towards the central line, and bent to exactly the same extent as the parallel rays were.

They will thus be brought to a focal point, just as the parallel rays were, but the point will be a greater distance behind the lens, because the lens has had a divergence to counteract which it had not in the case of parallel rays. The path of these rays is represented by the dot and dash lines in the figure(—.—.—.), and it will be observed that those lines *b* come to a point *b'* further away behind the lens.

If the point from which they come be a little closer to the lens—if, in other words, the divergence be a little greater—the lens will have power to completely counteract that divergence, and to bend them towards each other until they become parallel, and on their emerging from the lens they will go on to infinity, neither separating nor coming together.

But suppose the rays come from a point nearer to the front of the lens than that distance, *i. e.*, suppose them to be in a still greater divergence from each other, then the interposed lens will still bend them together to exactly the same extent, but it will not have power to bend them sufficiently to make them parallel, much less to bring them to a point, and on their emergence from the lens they will still diverge from each other, but in a much less degree than they did at first, and will pass off to infinity never to meet again unless another lens catches them and brings them together. The path of such a ray is represented in the figure by the dotted lines *c*—*c'*.

Let us now apply these facts to our own vision. In the normal healthy eye the refractive or bending power of the combined lens, which is formed by the cornea-aqueous humour and crystalline body, is *exactly* sufficient to bring the rays proceeding from a distant object, *i. e.*, parallel rays, to a point on the sensitive surface of the retina, as represented at *a* in Figure 2. The normal eye, therefore, in receiving light from the objects around us is in a state of perfect rest, and acts simply as an inanimate optical instrument as long as the rays received are not appreciably divergent. In fact, the focus of parallel ray, which is represented by the continuous lines *a*—*a'* in Fig. 1, exactly touches the retina, and falls neither before nor behind it. But if the object be moved towards the eye until the rays strike the cornea in a slightly divergent direction, the combined lens would still be capable of bringing the rays to a point, but that point would be at a proportionately greater distance behind the lens, and would fall, not on the retina, but at some spot behind the eyeball, and if there were no means of giving them a still greater convergence, they would strike the retina in a scattered form, and a blurred image would be the result. In fact, if the eye were an inanimate optical apparatus, no near object could be accurately discerned without placing in front of it a lens which would bring the divergent rays to parallelism before they entered the cornea. The accommodative power of the lens obviates this difficulty, and it is this capacity of increasing its own refractive power, or rather of allowing of an increase in its curvatures, which gives the crystalline lens such importance in the optical mechanism of the eye, for if such power did not exist it would be necessary for us to assume spectacles every time we required to read or to see a near object. For a very long time the accommodative power of the eye was a subject of investigation and speculation. As Donders says: "Since Kepler's first attempt to answer the question as to what that power consists in, the inquiry has been a source of much difference of opinion among natural philosophers and physiologists. All imaginable hypotheses have been advanced. Alteration of situation of the lens, elongation of the axis of vision, contraction of the pupil, change of form of the lens have all in turns been made use of in the explanation, and those who were satisfied with none of these theories were sometimes bold enough altogether to deny the existence of an accommodating power."

This accommodative power, it was evident, must be muscular in its nature, for it is voluntary, and we know of no physiological act which depends on the will except muscular contraction or relaxation. It is also evident that the increased power of converging the rays upon the retina could only result from one of two causes—viz., the approach of the lens to the retina, or an increase in its refractive strength or that of the cornea.

The former of these hypotheses was supported by the imaginative existence of a muscle running from the sclerotic through the vitreous to an attachment in the posterior capsule, which, however, was incapable of demonstration, and, in fact, did not exist. The evidence being strongly against any change of position of the lens—which, it may be observed, should have been considerable in extent to produce the requisite accommodative change—it was supposed that the iris was the agent in accommodation, and that it acted by contracting the pupil and thus shutting out all the rays but those which entered the centre of the lens. It is still stated that contraction of pupil takes place on accommodation to near objects, but that this act is not the essential cause of the optical change was proved by the condition of a patient under the care of Van Græfe, whose entire iris was torn out by an accident and the accommodative power remained to its full extent. Without following further the many hypotheses which were put forth to account for accommodation, it is sufficient for me to say that it has been conclusively proved that the lens is the essential agent, and I will proceed to explain to you how this has been shown to be the fact, what the changes are which it undergoes, and by what agency they are produced.

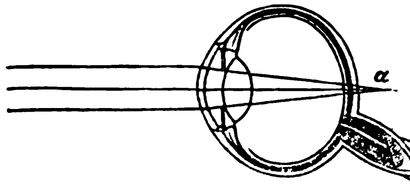

Fig. 2.

THE NATURAL HISTORY OF PULMONARY CONSUMPTION.

By A. B. Shepherd, M.A., M.B., F.R.C.P.,
Physician to the Victoria Park Hospital for Diseases of the Chest; Assistant Physician to St. Mary's Hospital; &c.

LECTURE III.—*Concluded.*

The title I choose for these lectures debars me from speaking with the faintest air of authority, or to any extent, of the various drugs used to oppose the ordinary course, and therefore considered to have some effect on the natural history of consumption. The key to any rational treatment of the disease is probably to be found in a careful consideration, in any individual case, of the present condition of the phthisical process—whether it be still active or for the time being stationary; and of the constitutional habit of the patient—whether of the weakly excitable type characterised by excessive reaction, or of the vigorous more heavy one, in which reaction is less marked (cf. Braun). But of one medicine, or rather food, I must speak briefly, because, in its effects on the patient, it offers a distinct bedside result. To use the words of a former President of the College, "you may learn much (and so, no doubt, you ought) by prying into the arcana of the night-chair" (*a*) and yet, in these days of numberless instrumental aids to diagnosis, the learning gained from that inspection, like the splendid knowledge of the pulse and appreciation by hand of increased temperature which marked a generation happily not passed away, seems to be in danger of leaving us, who more unworthily trust to mechanical assistance. But an inspection of the night-chair of a consumptive patient taking large quantities of cod-liver oil will reveal, as perhaps physiological theories ought to have predicted, a very great increase of fatty or oily matters evacuated. This, again, is no new observation, though it is one, I think, which may well teach us its lesson. Over twenty years ago, Sir William (then Dr.) Gull had recorded (*b*) his own observations on "fatty stools from disease of the mesenteric glands," and written down in no half-hearetd way his opinion as to the careless and utterly unscientific use of cod-liver oil. It cannot be denied that, by some means or other, this drug had, I might even say still has, come to be looked upon as a "specific" for "consumption"; and I use the word as our patients use it, as I have used it in these lectures—as consumption from disease of the lungs. Patients themselves tell us they must have phthisis, because the doctor who prescribed for them gave them cod-liver oil. At any rate, in hospital practice later, I repeatedly examined the fæces of phthisical patients, perhaps because the teaching of the wards of Guy's was unconsciously with me; and I found, as every one who performs the same experiment will find, that in these phthisical patients, beyond a certain amount of oil administered, varying of course in individuals, but, on the average, four drachms daily, large quantities of it pass through the intestines almost unchanged. And to this simple waste, not too much to be decried, is superadded very often increased disturbance of digestion and nutrition. Still, to quote Sir. W. Gull, "if it be ever admissible to limit the attention to one organ in treating disease, it is so" here, where "the condition of the gastro-intestinal membrane is of paramount importance."

And what I have said with respect to cod-liver oil, and its possibly harmful waste, applies quite as much, if not more, to a highly vaunted drug, which, to judge from the weight of an ordinary pig's pancreas, would demand for each patient, if I be not very wrong, hecatombs of victims; unless, indeed, there be a peculiar breed of swine with a larger pancreas,

"οὓς ἔθρεψε συβώτης ὀρχαμος ἀνδρῶν."(*c*)

Only a fortnight ago, a gentleman who had taken the emulsion had noticed for himself the fatty nature of his stools: a fact which my remark as to one of the effects of cod-liver oil led him to mention.

In approaching rapidly the close of my subject, I cannot but congratulate myself, representing for the moment the youngest Fellows of the College, that the work of the very latest time leads to a conclusion which in its pathological results, though not at all in its reasoning from those results, has the support of the perhaps oldest living authority on pulmonary consumption in this country. Dr. C. J. B. Williams, in the discussion to which I have already referred (*a*) has given us his "explanation of the twofold seat and origin of tubercle, or rather of consumptive disease: 1. Lymphatic, which is miliary, infective, and scattered; 2. Inflammatory, which is diffused in form and local in extent."

I would call the attention of those gentlemen who wish to examine them after the lecture to the microscopical preparations placed on the table of the various forms of pulmonary consumption described. [Explanations of the preparations, &c., followed.]

To sum up briefly the views, by no means original, which I have attempted to support respecting pulmonary consumption in these lectures, I am disposed to conclude:

That in the affection to which the name "acute general miliary tuberculosis" is given, the hard nodules occurring in the lungs are due mainly to growth of the perivascular and peribronchial cords, together with alveolar catarrh of smaller or larger extent.

That this perivascular growth is secondary to a cheesy focus not necessarily present in the lungs.

That the commonest form of pulmonary consumption in this country is due, in the first instance, to an intra-alveolar and intrabronchial catarrh, accompanied by proliferation of the epithelium more or less rapid; followed generally by impermeability and disappearance of the alveolar capillaries, and by changes in the septa of the alveoli; and resulting in the destruction of lung-tissue: the whole process giving rise to the clinical symptoms of phthisis.

That the same clinical symptoms of phthisis are caused by the pathological changes present in chronic bronchitis and emphysema, and in other cases by fibroid growth of the alveolar septa themselves, leading to the disappearance of their cavities.

That catarrhal pneumonia is the most common accompaniment of any affection of, or even injury to, the lungs; and that its occurrence often gives rise to the appearance of bodies possessing, to the naked eye, all the characteristics of the "tubercle" of authors.

That there is nothing in common between the pathological results of acute tuberculosis and those of chronic cheesy degeneration of the lungs, except it be in the occasional presence in the latter of the secondary lymphatic (?) products almost always, if not always, to be found in the former.

That the cheesy form of pulmonary phthisis ought not to be looked upon as one absolutely hopeless and fatal.

That, in the majority of cases of this form of phthisis, the whole bent of our treatment should be against repeated and chronic inflammations of the lung, in the sense of catarrh of the air-vesicles and finer tubes, and as far as possible in aid of increased assimilation and nutrition, especially in the encouragement of those methods of hygiene which consist not only in change of air and climate, but in the more ordinary matters of baths and suitable clothing.

And, Sir—to pause for one moment—the mention of these hygienic measures reminds me that, since our meeting here on Wednesday last, the College mourns the death of one of her greatest ornaments and most illustrious Fellows, Professor Parkes of Netley. Further of him to-day it is not for me to speak.

Portal, publishing his work on the *Nature and Treatment of Pulmonary Phthisis* in "the first year of the

French Republic,' as his title-page tells us (1792), speaks more boldly than did Bayle, who, with some sort of solemn religious feeling, confesses that to a large extent he has not dared to "explain the part that Nature plays in the production of phthisis." (*a*) But Portal, conceding that medicine is but a branch of natural history, thought he could not do better than conform strictly to the method followed in the different portions of the latter: that is, to give a history of facts observed, arrange them in order, and draw from their comparison the true character of the object treated of. "We ought never," he says, "to hope to guess at or to domineer over Nature; we can but listen in silence to, and meditate attentively over, the phenomena we observe; we can but discuss them carefully, and gather from them such truths as shall be useful." My aim has been to work after this fashion.

In conclusion, Sir, if I have not in very word complied with the conditions of the bequest of Dr. Theodore Goulston, "that a dead body was, if possible, to be procured, and two or more diseases treated of," I have at least brought the pictured results of the post-mortem room within the College, and treated, however imperfectly, of an affection which is Protean in its anatomy, if not in its features. Following out, at any rate, the feeling which, as Censor of this College between the years 1615 and 1626, he had probably attempted to inculcate, that not without the scalpel would the bounds of knowledgd be widened, I may say, in the words which his perhaps greater successor in this Fellowship makes use of, "Non solum manus pro virili medicas languidis corporibus adhibendi, verùm etiam defunctorum cadavera introspiciendi quàm sæpissimè ansam arripui." (*b*) Yet it may be that whatever I have said on the subject I have had the honour to bring before you only illustrates once more the twice-told sentence of Bacon: (*c*) "The spirit of man feigns in Nature a simplicity and uniformity greater than really is." It may be that the conclusions to which I have been almost irresistibly led as to what seems to me to be the simple nature of pulmonary consumption may fail to be real, when scanned by some more searching eye than my own; and if it be so, for work at least honestly attempted some consolation may be found in the words in which Heberden speaks of the uncertainty of modes of treatment: "No aphorism of Hippocrates holds truer to this day than that in which he laments the length of time necessary to establish medical truths, and the danger, unless the utmost caution be used, of our being misled, even by experience." (*d*)

◆

ANIMAL VACCINATION. (*e*)

THE VACCINAL STATE INSTITUTE OF BRUSSELS, CREATED BY ROYAL DECREE OF JULY 11, 1868.

Under the direction of Docteur WARLOMONT, Membre Titulaire of the Royal Academy of Médicine of Brussels.

(Translated at his request by Dr. C. R. DRYSDALE, of London.)

IN all civilised countries vaccination is accepted and practised as the most certain and even the sole preservative against small-pox. Vainly, from time to time, do some sceptics still cast doubts on its value; their opposition no longer serves but to make a truth long known more living, and convincing.

The objections made against vaccination are of two kinds: some say that it tends to shut up in the organism some morbid principles which an attack of variola would have the effect and aim of removing from the system. Thus, it would be capable of giving rise to other affections quite as grave, the bursting forth of which it would only have retarded. Others - and this argument is especially addressed to the public—assert that it presents, besides, the uncommon danger of exposing the vaccinated to receive, in the act of vaccination, the impregnation with constitutional diseases which may belong to the persons who have furnished the matter for inoculation.

For a long time past the first of these objections, due to the statistician, has been met, and we need not return upon it. As to the second, we are forced to accept it as having foundation, at least to a certain extent, and as far as syphilis is concerned, and we cannot refuse to give satisfaction to those who, in face of the compulsion made use of where vaccination is legally obligatory, experience a repugnance, the legitimacy of which cannot be contested, in presence of facts which, if they may have been considerably exaggerated by public credulity, are not the less met with periodically in practice.

We have been more than once reproached for having made use of such facts to aid our cause. We have replied that the reproach was unmerited. We said that it was an element in the question which required great consideration, and we repeat it. Besides, what good does it do not to confess it? Is the avowal of it not on the conscience of us all, and ought we, by refusing to explain ourselves, to believe ourselves safe, like an ostrich when it has hidden its head beneath its wing?

What satisfaction can be given to these disquietudes or to these repugnances? This has long been pointed out. It is sufficient that the vaccinator should take care only to accept as vaccinifers those individuals who are healthy and well made, and especially, seeing the difficulties which surround such selections, that he do not charge his inoculating instrument with any but pure lymph, free from all mixture with blood or different secretions of the subject that furnishes it.

All, however, is not said when this recommendation has been given. Let us admit that it has been rigorously observed—and that is a great admission, for we know how many culpable negligences follow in the train of a daily practice which has for long proved inoffensive—do we not know how inclined families are to lay to the account of vaccination the morbid symptoms which may attack their children, and how few among them take the trouble to investigate how much foundation there is for their deductions? Hence a source of mistrust, under which too many patients shelter themselves, in order to justify either their negligence or their resistance to the prescriptions of law and of hygiene.

Here, then, is a first desideratum to remove. There is also a second, which it is not less important, to put on one side. I would speak of the relative penury of vaccine lymph.

In countries where obligatory vaccination flourishes, in England, for example, where every infant, at whatever season, not only must be, under the penalty of a fine or even imprisonment for its parents, brought by them for vaccination, within three months after birth, but where they are liable to the same fine if they do not bring it again on the 8th day and allow it to be used as vaccinifer, the penury of vaccine matter can hardly be felt, and, in this point of view at least, its sources do not require to be renewed. But how different is it not in Belgium and in France, for example, where vaccination is left to the will of the parents, and how important it is to preoccupy ourselves about this point. There, not only do the parents, when such is their caprice, neglect to vaccinate their children, but what is almost as grave when the quantity of disposable lymph is concerned, may refuse, if it be their pleasure—and there is no lack of such parents—to allow the least particle to be taken for the benefit of others. This is not all; there reigns in many places the prejudice, that it is dangerous to vaccinate children in winter; hence, an almost complete suspense of operations from 1st October until 1st May, that is to say, for seven months of the year.

We see the consequences of this state of things: an

(*e*) The information contained in this work was furnished to the Members of the International Medical Congress when they visited the Vaccinal Institute of Brussels (September, 1875).

epidemic of small-pox manifests itself in winter, and with it the need of a great quantity of vaccine to meet the demands of revaccination; the lymph is wanting, or at least its production is not proportionate with the demand. The practitioners of depôts, of maternities, and of institutes of human lymph, may exhibit at such time prodigies of goodwill and activity, the subjects are wanting, and they are thus reduced to be more easy in the choice of the vaccinifers, and to distribute even—who knows?—vaccine matter from revacciuated persons, which nine times out of ten does not merit any confidence, and, when used in revaccinations, creates a security the more dangerous, that all control drawn from the results is in this case impossible.

Thus, in centres where vaccination is not obligatory by law, there is public utility in adding to the sources of vaccine by means which are not at the mercy of the public.

We have recognised above that, in others, this utility is less felt, because vaccinifers are there rarely wanting, and that there, in consequence, new processes would do ill to wish to be enforced, because of the insufficiency of the Jennerian lymph.

This, however, is but one of the sides of the question. There is another on which we have already insisted above. In countries where there is obligation for parents to vaccinate their children there is also a moral obligation for the State to furnish to such families vaccine lymph which shall be free from any shade of suspicion with regard to adulterations of diseased conditions.

Such are the two failings in the vaccination made use of since Jenner, and for which it was important to seek an efficacious corrective by the aid of new resources. These resources have been found by us in the practice of what is now conventionally styled "animal vaccination," a method which consists in sowing the original vaccine matter on young subjects of the bovine species, and making serve for the vaccination of mankind the produce of this culture. This product, besides escaping from the danger of diathesical adulteration, may be, with but short delay, infinitely multiplied, and create an unlimited source of vaccinal lymph capable of responding almost at a moment to the most imperious and extended necessities. Well, it was these two results which were to be obtained, and which the Belgian Government has attained to by creating, at my proposition, by a Royal Act of 11th July, 1868, a special establishment, which has been called "Institut Vaccinal de l'Etat."

Here is the text of this Act :—

Leopold II., King of the Belgians, to all present and to come, salutations. Having seen the reports made to the Royal Academy of Medicine as to the opportunity for renewing vaccine lymph by the inoculation of spontaneous cow-pox on calves, as well as the conclusions adopted in this matter by the Academy in its meeting of March 30, 1867, thus formulated :

1. The Academy has already recognised the utility and even the necessity of renewing and refreshing vaccine lymph, and has not changed its opinion since.

2. A really practical method of obtaining this renewal would consist in a large application of animal vaccination, founded on the inoculation of spontaneous cow-pox on calves, on which the product of this inoculation would be constantly kept up by the processes recently introduced into science. Having seen the opinion given forth in this same direction by the Conseil Superieur d'Hygiène Publique on April 26, 1865,

On the Report of our Minister of the Interior,

We have enacted and now enact :

Art. I.—The dispositions of the Royal Act of April 18, 181[illegible], concerning the medals spoken of in Art. 9 of the said Act are reported.

Art. II.—By means of the fund set aside for the payment of the said medals, there shall be created by the cares of our Minister of the Interior a special service with these objects :

1. The renewal of vaccine actually made use of by means of animal vaccination, founded on the inoculation of spontaneous cow-pox on calves, on which the product of this inoculation shall be constantly kept up by processes recently introduced into science.

2. The gratuitous distribution to all practitioners in the country, and to the communal administrations of localities which have no medical man, who shall make the demand in writing, of vaccinal matter thus obtained, as well as of humanised vaccine, product of the vaccination from the calf to the arm.

Art. III.—The chief of this service shall have the title of *Director of the Vaccinal Institute of the State.*

Art IV.—The Director of the Vaccinal Institute of the State is charged—

A. To see that there is constantly, in the place set apart for this purpose, at least one calf vaccinated by his care, by means either of the products of the spontaneous cow-pox discovered at Beaugency in 1866, (*a*) and kept up since then at the vaccine office of Dr. Warlomont at Brussels, or by means of the spontaneous cow-pox which chance or researches may cause to be discovered in this country or abroad.

B. To collect the cow-pox furnished by the calves, according to the processes recognised to be most advantageous, and distribute it gratis, under the conditions to be mentioned by-and-by.

C. To vaccinate infants from the calf to the arm, in order to be able, in the limits of the possible, to distribute, also gratuitously, humanised vaccine lymph, of the first transmission, which some vaccinators may prefer to the cow-pox, which comes directly from the calf.

D. To avoid lest any interruption take place in the successive inoculation of calves.

Art. V.—The gratuitous distribution of vaccine lymph collected at the Vaccinal Institute of the State is limited, as well for the vaccinators as for the communal authorities, to the sending out of two tubes or two points of vaccine lymph annually. (*b*)

The Director of the Vaccinal Institute shall be, however, obliged to satisfy, as far as possible, all the demands for vaccine lymph which shall be made to him, but he may ask from the communal administrations one franc, and from practitioners a fee of two francs per tube or point of animal matter, for any quantity sent exceeding the limits above mentioned. He is also authorised to deliver vaccine lymph at the rate of two francs per tube or point to any private person making a demand for it. (*c*)

By Royal Act of July 11, 1868, Dr. Warlomont, Membre Titulaire de l'Academie Royale de Médecine, is named

---

(*a*) M. Pétry, Titular Member of the Royal Academy of Belgium, pointed out to this company, in a meeting of the 11th of this month, a case of spontaneous cow-pox discovered by him at Esneux (Liège) on the 2nd of July, and laid on the desk the minutes in due form of this discovery.

He makes this known at the same time that Dr. Warloment, informed of the fact by telegraphic dispatch, hastened to betake himself to the place and to collect the vaccinal matter, which he inoculated with complete success on one of these calves.

(*b*) The direction since then has spontaneously engaged to furnish vaccine to practitioners gratis, whenever they require it to renew their stock.

(*c*) It has been asked, and is sometimes still asked, if it were not well to suppress the emission of lymph to the public for money, an emission which, at first sight, appears incompatible with the exclusive character of an institution of public interest and the dignity of its aims, and consequently to decide that all lymph produced at the institute shall be distributed gratuitously. But it has been thought wrong—and not without reason—to deprive parents from the possibility of providing themselves, without any middleman, and from the fountain-head itself, with the sole kind of lymph in which many of them have placed their entire confidence; practitioners, in fact, not being able to address themselves to the institute for every subject they are to vaccinate, will continue to make use of a regenerated human vaccine lymph, which gives them perfect satisfaction, but which does not inspire perfect confidence in certain families. There would result from this tolerance a restriction voluntarily put upon the fees of an organisation which has been in vigour for the past six years to the satisfaction of the public, and which we ought not to touch without good cause.

Director of the Vaccinal Institute of the State.—*Moniteur Belge*, July 14, 1868.

Independently of the two wants we have above referred to, that is the danger, real or imaginary, of the transmission of diathetic diseases and the possible and often real penury of lymph to inoculate, a want which it was necessary to cause to cease, the Royal Decree aims at a third object—the renewal and refreshing of the ordinary lymph of the stocks. This object is not of less importance than the others. There is not, indeed, any vaccinator who has not sometimes seen, at a given moment, and without any very appreciable reason, the vaccine pustules of his patients gradually taking on a less flourishing appearance and become weakly or even ceasing to be produced. Does this mean that the lymph is thus weakened spontaneously or by the effect of time? This hypothesis is not proved; but what is proved is that it is sufficient that the germ has passed through a weak organism or a cachectic person in order to render it in its turn a less vigorous product, which gradually shall finish by becoming quite extinct. The existence of an establishment where the practitioner can in these cases of falling off renew and refresh his stock has then a real and incontestable utility, and we do noe think it necessary to lay much stress on it.

The Vaccinal Institute of the State has been in operation in Belgium for about five years, and, excepting some criticisms of details relative to its organisation, has been received with the greatest favour. Should it be wished to know in what proportion practitioners have made use of it, here are the figures: of the 2,000 practitioners nearly who practise in Belgium, we may estimate that hardly one-half, or 1,000, occupy themselves with vaccination. Well, of this number, 305 had recourse to the animal vaccine of the State in the one month of June, 1873; 463 in the course of the month of July of the same year; or in short, 768 in the course of two months. Since that time these figures have been notably higher; they have their eloquence.

Is the vaccine furnished by the Institute worthy of this confidence? Here is our reply: Employed living, that is from calf to arm, when the vesicles are well out and accuminated, that is, in the course of the fifth or sixth day, according to the season, animal vaccine lymph inoculated on virgin subjects is destitute of any faults, save those which arise from the hurry or unskilfulness of the operator. Well inoculated—and with the *living* lymph mere punctures suffice—it gives as many vesicles as insertions are made, and these may sustain comparison with the most beautiful products of human vaccine. If preserved vaccine be in question, and here we specially speak of the dry lymph preserved on ivory points, according to the mode adopted by us borrowed from England, we shall draw our reply from a report consigned in the *Bulletin de l'Academie Royale de Médecine de Belgique* (1871, p. 1217), whence it results, that the vaccinations and re-vaccinations which took place in 1870 and 1871 in the hands of 369 of the most well-known practitioners in Belgium, by means of points delivered by the Vaccinal Institute of the State, have given the following results:

1. In the vaccinations, of a total of 500 cases, 479 successes, or 96 per cent.
2. In re-vaccinations, in a total of 5,425 cases, 3,419 successes, or 62 per cent.

These are figures superior to those quoted in all statistics, for in England the best vaccinators only value at 90 per cent. the figures of their successes in vaccinations by means of human vaccine in tubes, and at 95 per cent. that which is procured by the same lymph on ivory points.

It remains to be established what is the reality of the preservation procured by animal vaccination, and again, the duration of the preservative virtue. As to the first point, this has to be replied, that out of more than 10,000 infants vaccinated at Brussels by animal vaccine, from 1865 to 1870, and which passed through the terrible small-pox epidemic which in 1870 and 1871 terrified us all, there has not been pointed one as having been attacked with the pest; that the same absolute immunity has been shared by our re-vaccinated cases, which are far more numerous, and who at the same time were in the midst of the foci of the epidemic. As to the durability of the preservation, it must be permitted to us to allow time to fix its duration.

There are many countries where parents do not permit the practitioner to take their children to serve as vacciniers; others, again, where they only consent to it for money. At Paris, if I am well informed, a good vaccinifer is paid five francs. Here the evil is not great, since the remedy lies near; but how many mothers do we not meet who repulse with horror all pecuniary offers. "Allow my child to be tortured for money, never!" and the finest pustules disappear unfruitful for any other child.

(*To be continued.*)

Clinical Records.

OBSTETRICAL MEMORANDA.

Reported by John W. Martin, M.D.,
Assistant-Surgeon, Mayfield Factory, Portlaw, &c., &c.

The record of clinical experience, even of a very ordinary nature, is likely to prove both interesting and instructive to the junior members of the profession, from the fact that such a record illustrates the doubts and difficulties with which we are assailed in the fulfilment of our daily duties, and the manner in which they have been met, and where possible, overcome. Such a conviction must be my apology for the publication of the following notes of some obstetric cases which have fallen under my notice; they present no unusual features, but are fair examples of the ordinary difficulties to be met with in this branch of our profession.

Case I.—*Mrs. M'C———, æt.* 28, *over two years married.—First Pregnancy.—Cord twice round Child's Neck, once round Body.*—I was asked to see this patient, 11 a.m. March 28th, 1876, the end of the eighth month of pregnancy, she having ceased to menstruate July 28th, 1875. Her labour had commenced at 1 a.m. The nurse in charge desired my presence, as the pains were irregular in their recurrence, and severe in their nature; no progress had been made during the 10 hours they had lasted. On examination, I found the passages well formed, cool, and moist; the os uteri was high up, close to the promontory of the sacrum, and dilated to the size of a shilling; waters unbroken and presenting with each pain; the head was the presenting part of the child; she passed water freely; the bowels had been confined for some days, but the rectum was, comparatively speaking, empty. Pulse 84, regular and even; stomach inclined to be sick. She was rather wearied by the loss of her night's sleep, and by futile efforts to help on her labour. I ordered her to rest herself as much as possible, not to weary herself in any way during a pain, and to take some strong beef-tea and other nourishment in small quantities. Saw her again at 2 p.m., but very slight advance had been made in the dilatation of the "os." The pains were very strong, but still irregular. She had taken nourishment freely; complained a good deal of being weak and wearied. Pulse good. Parts still cool and moist. Ordered a large warm water enema, containing sugar and salt, to be given, and repeated in four hours' time, as I have found such enemata very useful in provoking steady and well directed uterine action. At 7 p.m. I found matters but little changed. The enemata had steadied the pains, and so far served their purpose, but they had not brought away any fæces. The os was dilated to the size of a two-shilling piece, its edges were thin and resisting; the secretion of mucus in the passages had diminished, though the latter were still far from being hot and dry. The patient had taken a fair amount of nourishment during the day. The bladder emptied itself regularly. The patient felt weak, and wearied, and it being her first experience, she was naturally a little anxious about herself. I was somewhat puzzled to account for the delay. The patient was a strong and well formed young woman. The pains were evidently those of regular labour. The waters were unbroken; the child's head presenting; and everything seemed favourable to a speedy delivery. Added to this, there was also the fact, that she had barely completed the eighth month in pregnancy. I then injected ¼ of a grain of morphia in solution subcutaneously into the arm, close to the insertion of the deltoid muscle, which I find the most convenient place for this operation. She slept after it for half-an-hour; all pains ceased until about 10 p.m.; the pains then returned, but still remained ineffective, as before; there was no change in the condition of the os or passages. At 11 p.m. I repeated the injection of morphia, and left to take a few hours' rest. Saw her again at 2 a.m., the morning of the 29th. She had rested well since my last visit, and was not troubled much with the pains. She had taken nourishment freely, and felt stronger and better. The dilatation of the os had made slight progress, and I was pleased to find its edges becoming rounded, cushiony, and dilatable. Waters still unbroken, and the secretion of mucus much more abundant. Nausea more pronounced than it had been the previous evening. From a consideration of the general condition of affairs I felt convinced that there were as yet no grounds for instrumental or other interference. The fœtal heart was just as I could wish it to be, strong and regular. Ordered a dose of castor oil to be given, and left her again until morning in charge of the nurse. The morning visit was paid 15 minutes to 9 a.m. She had passed a quiet night, dozing, and free from pain. Did not retain the oil upon her stomach more than a few minutes. No action from the bowels. Passing water freely. "Os" dilated to the size of a crown-piece, the edges full, rounded, and dilatable. Passages cool and moist. Waters unbroken. Rectum full of fæces. Pulse 84, full and even. Felt much refreshed for the night's rest, and took plenty of nourishment, notwithstanding frequent attacks of nausea and occasional vomiting. The pains had just recommenced before my seeing her, and were recurring regularly and with moderate severity. No change in the fœtal heart, and the presentation was all that could be desired. I directed a repetition of the enema, and left to attend to the morning dispensary, leaving orders with the nurse to send for me at once should any decided change take place. Before leaving I applied the binder as a support to the abdominal walls, and as an aid in maintaining the child in favourable apposition to the axis of outlet, at the upper brim of pelvic cavity. At 9 20 I was called away from the dispensary, the pains having increased both in frequency and severity and altered in character, being now those of strong "bearing down" efforts. The enema had acted copiously. The "os" was fully dilated, but the anterior lip was low down in the passage; the waters were still unbroken. Rapid delivery was anticipated, as the passages were very spacious and well formed. The waters broke at a quarter to 10 a.m., and the head engaged the upper brim of the outlet, tightly jamming the depending anterior lip in its descent. I had some little difficulty in pushing this up and retaining it in position until the head was sufficiently low down to prevent its prolapse. It finally disappeared at a quarter past 10 a.m. The head of the child engaged the floor of the perinæum at a quarter to 11 a.m., and delivery was completed at 11.20 a.m. The left hand of the child was to its head; and the cord was *twice round its neck* and once round the body, besides being rather short than otherwise. This last complication puzzled me for the moment how to deal with it, as I had never seen such a case before. I found it impossible to free the cord from the child's neck, and my efforts merely threatened to make matters worse, by tightening the strain upon it, thereby increasing the risk of strangulation, from which the child was in imminent danger. The expulsive efforts of the mother towards the delivery of the shoulders threatened the same result. I at once applied the ligatures, divided the cord, hastened on delivery, and restored animation by practising Sylvester's method of artificial respiration. The child had uttered one or two cries immediately after the birth of the head, but subsequently became livid and lifeless in appearance. It was from eight to ten minutes before respiration was re-established. It was a fairly developed infant, its general appearance coinciding with the statement of an eight months' pregnancy. The placenta came away in ten minutes, its expulsion being hastened by moderate pressure applied to the fundus uteri; its separation was accompanied by a smart dash of hæmorrhage, but none subsequently. The uterus contracted firmly. Immediately after the delivery of the placenta I gave ʒss. dose of liquid ext. of ergot. The binder already applied was tightened evenly and comfortably. I remained an hour in the house, saw the child put to the breast, and did not leave until assured that my patient promised to do well, a promise verified by her subsequent speedy and satisfactory convalescence. Her labour had lasted nearly 36 hours.

Remarks.—It is unnecessary for me to discuss at any length the question whether this case was one for instrumental delivery or not. Its history negatives the idea at once. Until the morning of the 29th, there was not sufficient dilatation or dilatability of the "os" to warrant the introduction and use of the forceps. There was no excessive uterine action threatening rupture of the walls of the uterus, or dangerous pressure upon the cervix and maternal passages. The dilating force was applied through the unbroken bag of waters. The patient's strength was good, and with support and management promised to continue so, and to carry her safely through. Her pulse remained firm and even throughout. The fœtal heart also was all that could be desired.

Taking all these facts into consideration, I made up my mind to wait patiently upon the powers and efforts of nature, with, as the end showed, the happiest results.

I would direct special attention to the favourable action of the opium given in this case. In mine and the hands of others it has proved most beneficial as an alterative to the condition of the "os," where this is becoming thin, hard, and resisting. This state of the "os" I regard as very dangerous indeed, if the waters have broken, and the head of the child is pressing down upon the cervix, from what I deem to be an increased risk of fissure and rupture of the uterine walls in this position. The utility of opium under such circumstances was first impressed upon my mind, and indelibly so, by a case which I attended, in conjunction with a fellow-student, in Edinburgh. He was taking out his prescribed course of attendance upon the outdoor patients of the Maternity Institution of that city. It was his first case, and as I had already completed my course of study at the Rotunda Hospital, Dublin, and held its L.M., he asked me to accompany him. We were called at about six o'clock in the morning, the woman having been in pain throughout the night, from about twelve midnight. She was a poor laundress by occupation, and in rather indigent circumstances, not very strong or well nourished. On arrival we found the "os" dilated to the size of a florin-piece. The edges were soft, rounded, and dilatable. Pains strong and regular. Everything seemed favourable to a speedy and happy conclusion. Being tyros deeply impressed with the importance of our charge, we remained in close attendance the whole day. As the latter wore on, the pains became weaker, at the same time increasing in frequency and very "nagging." The woman got little rest between, and felt weak and worn out. The lips of the "os" changed their character; they became thin, tense, and resisting, imparting to the finger the sense of being opposed by a bit of whip-cord very tightly on the stretch. There was diminution in the secretion of mucous in the vagina, the parts tending to become hot and dry. The waters burst about 4 p.m.; matters were thus aggravated, by the pressure exerted by the head, the presenting part, upon the cervix. We got some new milk, and Liebig's essence of beef, and gave nourishment to her freely. Though somewhat strengthened and refreshed thereby, matters remained much the same up to 7 p.m. I then thought the indication was plainly to secure rest for some hours, giving time to the uterus to recover itself; accordingly, I gave a full dose of Battley's sedative, gtt. xxx., in a draught. In twenty minutes the pains almost ceased, and the patient rested quietly until 10 p.m., taking nourishment at the same time freely. It was interesting in the extreme, watching the change in the condition of the "os uteri" and vagina. The parts before tending to dryness became bathed in mucus. The lips of the "os" soon became thick, rounded, cushiony, and dilatable. Dilatation went on rapidly, although unaccompanied by much pain. About 10 p.m. we gave a large warm-water enema, which brought away some fæces, and excited a renewal of uterine action. Just at midnight our patient was safely delivered of a fine full-grown and well-formed child, and convalesced without an accident. It was one of the most interesting and instructive cases I have ever had the pleasure of attending, and gave me a truer insight into the management of a patient in labour than I could ever have acquired by months of hard reading. Another point upon which I desire to touch is the application of the binder previous to delivery. It is a useful measure in most cases, specially in those in which the abdominal walls are thin, weak, and pendulous. It affords great comfort and support to all; at least, such has been my experience, whenever I have applied it. Sometimes by accompanying each pain with steady, firm, and at the same time gentle traction upon the binder, the expulsion of the child may be hastened. Of course I claim no originality in its application; I am merely recording the result of my experience in the use of it. As for the administration of ergot immediately *after the expulsion of the placenta*, in fairly large doses, as advocated by so many of the heads of the profession in this special branch of our art, my experience is entirely in favour of it. I make it a regular practice in all the cases I now attend. At the same time I am convinced there is but little danger of P. P. H. if the uterus is not allowed to exhaust itself, by the due exhibition of nourishment in concentrated form, such as strong beef-tea or chicken broth, eggs broken up with a little brandy and boiled milk, and by the free use of the latter whenever a drink is required; also by the use of opiates where necessary. To keep up the patient's strength in each confinement is my first object, to secure physiological rest, and time for the uterus to recover its strength, the second. The necessity for doing so is at once apparent, if we bear in mind the widely different results attending *continued*, and increased *intermittent*, physiological action in the case of muscular structures. In the case of the first, there is exhaustion and atrophy; in the case of the latter, increase of power, and hypertrophy. Indeed this law holds good in the case of every tissue and organ in the body, and therefore must not be forgotten when dealing with the uterus in the hour of its trial. In many cases where this fact has been borne in mind, and nourishment and opiates have been freely and judiciously used, I have seen good strong contraction in uteri, which I am convinced, under other treatment, would have been relaxed, and from which there would have been abundant P. P. H. Before concluding this communication, let me impress upon my junior brethren the absolute necessity that exists for a careful education of the sense of touch in all that relates to midwifery as far as labour is concerned. To see with the tips of their fingers as clearly as with the eye itself must be the object of their ambition; and the more completely they can do this the less will be their difficulties in any given case.

REGISTERED FOR TRANSMISSION ABROAD.

THE
MEDICAL PRESS AND CIRCULAR
is published every Wednesday morning Price 5d. Post free, 5½d.
POST FREE TO ANNUAL SUBSCRIBERS £1 2 6
„ IF PAID IN ADVANCE 1 1 0

*** Post-office Orders and Cheques to be drawn in favour of—
A. A. TINDALL, 20 King William Street, Strand, London, W.C.
A. H. JACOB, 23 Ely Place, Dublin.
MACLACHLAN and STEWART, South Bridge, Edinburgh.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIERE, Rue Hautefeuille, Paris—post free in advance, £1 5s. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLMER and ROGERS; Baltimore, by Messrs. KELLY and PIET; Philadelphia, at the *Medical and Surgical Reporter* Office, post free in advance, £1 5s., about six and a-half dollars; or direct from the Offices in this country for the same amount, by International Post-office Order.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 19, 1876.

THE VIVISECTION BILL.

THE Deputation which waited on Mr. Cross at the Home Office last week to urge objections against the Vivisection Bill has already had a good effect.

The *Times* which a short time ago expressed itself in favour of legislation upon this subject, has now recognised that the Bill before Parliament is calculated to do an injustice to men of science, to the medical profession as a body, and to retard the progress of science. We cannot believe that the Bill will be carried as it stands. If a majority of the House of Commons can vote in favour of such a law we cannot but conclude that either the Dark Ages are coming back upon us, or that the representatives of this country are unfitted to govern the nation. Two thousand members of the profession signed the memorial which was presented to the Home Secretary, and we may say that if the whole body of the profession were canvassed the expression of opinion would be all but unanimous in favour of that memorial.

The *Times* says we have only to consider a parallel case to estimate the weight which must be attached to such a demonstration. If the whole legal profession in a body protested against some measure for regulating the practice of the Bar, or if the whole body of actual and possible Academicians remonstrated against a measure for restricting the study of Art, the public would at once come to the conclusion that some material error or injustice was contemplated by a measure thus opposed. In any case which leaves room for doubt there is always a strong minority, at the least, of professional experts who differ from the predominant opinion of their brethren. But in this instance the feeling is equally strong and unanimous. All the men to whom humanity is at the present day most indebted unite in one indignant remonstrance against the measure.

A man may grow up to be a distinguished physician without ever having so much as witnessed such an operation. What most know of the practice is simply that its results are often invaluable, that it is practised by their brethren with the greatest reluctance and under the most humane motives, and that the men whom it is now sought to subject to this legislation are among the most unselfish and gentle of their profession and their race.

When the public read the able article in the *Times* of Wednesday last we doubt not that many will be convinced that the agitation has been stimulated by either ignorant or designing men, and that the hordes who have signed petitions against vivisection for scientific purposes have done so under entirely erroneous apprehensions.

Some twenty earnest workers represent all those of the medical profession who are engaged in the practice of vivisection in this country, and the good resuling to mankind and arising out of the observations of these twenty men is acknowledged on all sides, not only in this country but throughout the civilised world, and yet the medical profession have been attacked as a class of men specially addicted to the infliction of pain on the lower animals. The medical profession would be unwilling that these few men should be disassociated from the profession; they are in a way representatives of the whole body. It is in great part the ideas and suggestions of thinking physicians and surgeons that are worked out by those few men who are willing to investigate by experimentation upon living animals, but it has been explained and proved that these experiments have been and are being carried out in many instances without the infliction of pain whatever, and in all instances with the infliction of as little pain as is compatible with a correct observation of the point under investigation.

It has been shown again and again that the pain inflicted upon animals by scientific members of the medical profession is like a drop in the ocean compared with that which is daily inflicted upon them by men in their ordinary habits. In the one case the pain is regretfully inflicted with the object of saving human life and alleviating pain in man and animals. In the other case it is inflicted for the sake of gain or of pleasure by many of those very men who are leading the agitation against vivisection, and yet the whole force of the Government of one of the most intelligent of nations, stimulated by the wild shriek of an ignorant and hysterical and misinformed multitude is arrayed against the actions of these twenty men, whilst the infliction of pain on animals for gain or for amusement is connived at and encouraged. There is no gainsaying these statements; they are facts, and can be proved by any and every individual who will take the trouble to inquire; and neither can the matter be minced that men who can in the face of these facts legisiate to put down the one, whilst at the same time they themselves take part in the other, are not fit to hold office in the Government of this nation. The Home Secretary has already acknowledged the weakness of his position. He has said that it must depend upon the line of action taken by the profession whether the Bill passes this year or whether it is deferred to another session, in which case the people who are influenced by sentiment may not be satisfied with a Bill as liberal to the profession as that brought in by the present Government.

The Medical Profession are not likely to be misled by such arguments or to be coerced into the acceptance of the present Bill under such a threat. They will be probably willing that legislation shall extend so far as the granting of a license to those engaged in vivisection as a guarantee to the people that only capable men are engaged in the practice, and this is all that a government can fairly require.

It is unnecessary to refer to remarks made by the Home Secretary on Dr. Lyon Playfair's bill. It was never brought before the profession and it is not before them now.

We would suggest to every member of the profession that though he, as a medical man, is not interested in the question at issue, he is personally so as one of the public, and though he may have never given his mind to the subject, yet he never prescribes without unwittingly making use of a knowledge which is more or less the result of experiments on living animals, and it therefore behoves him to use his influence in throwing out this Bill. It is necessary that he should make himself acquainted with the arguments for and against vivisection, that he should be able to discuss the subject and disabuse the minds of the public concerning the scandalous falsehoods and libels which are now printed and freely circulated, and finally, we would say, it is a duty which every member of the profession should impose upon himself to thrust the discussion of the question upon those among his friends and patients who may happen to be members of the House of Commons, in order that those who have to decide whether legislation shall or shall not take place may be fully informed of the whole truth, and shall be able to recognise how *injudicious* and how *unjust* is the Bill which the government propose to enact.

◆

SCHOOL HYGIENE.

We are glad to see that this subject has been taken up by the Medical Society of New York. From a very recent number of *The Medical Record*, we learn that at the last annual meeting of the medical society of that State, the President, Dr. Rochester, remarked "that education was not, in all instances, the unmistakable blessing which it seemed to be, for it became necessary to acquire it at too great risks. His conclusions upon this point were that no child under ten should be sent to a public school and that every school district should have a competent and well-paid medical director, who should devote himself thoroughly and conscientiously to the many hygienic duties of his position. It would not involve an increased expense; on the contrary, it would be to the community a most economical proceeding. The society, as representing the profession of the State, should take some action which would inaugurate and perpetuate a reform in this respect."

We can all agree in admitting the justness of the above remarks, but unfortunately competition of all kinds, the struggle for the means of a comfortable subsistence, and the expense and inconveniences attending private tuition, are so great, that we are afraid it will be a long time before the public will be prepared, or allowed, to adopt the excellent advice suggested by our American conference. Now that compulsory education has been adopted in this country, and little children are compelled to go to school at a very early age, it is incumbent upon the Government to do all they can to see that the health, as well as the education, of the poor is not neglected. The necessity of some hygienic supervision of the children of the poorer classes is the more apparent when we reflect upon the dirty, miserable, and unhealthy conditions under which many of those children live and sleep, upon the bad habits and slovenly manner in which they are brought up, and even upon the dreadful examples which are often set them by their own parents. There can be no doubt that much of the bad effects resulting from the unhealthy physical and moral conditions to which the children of the poor are exposed, was, previously to the Education Act coming into force, in a great measure counteracted by the licence they then enjoyed of knocking about in the open air, or following some active employment. But now all this is changed; and if children of tender years are to go from homes in which they are badly fed, badly clothed, and badly brought up, to schools where the air is not much better than what they breathe in their own lodgings, or to schools where the hours of study, or the discipline of which is too much for their weak frames, or to schools where cleanliness and good moral conduct are not as strongly insisted upon as a knowledge of the three R's, then we say, that as far as the *morale* and *physique* of our future working classes are concerned, it would be better if School Boards and compulsory education had never been thought of.

Now, in order to obviate the evils which we clearly see may arise from the provisions of the new Act, we think that no better plan could be adopted than that which has been suggested by Dr. Rochester. If a competent and well-paid medical officer were attached to each School Board district, who, among other duties, would make an examination into the health of the children on their first entering the school, repeating the examination during the years at such period as the Board may think proper to fix, and who, moreover, would see that some of the ordinary principles of health, both as respect the pupils themselves and the school rooms, were not neglected, we should then, in all probability, have a class growing up around us whose physical, moral, and social status would be far above what it is now?

◆

THE ANATOMICAL FOUNDATIONS OF CHARACTER.

The progress of recent research in cerebral histology is teaching us many new views, and prominently among them, that all psychical manifestations are accompanied by corresponding actions in the cells of the grey matter, or cortical layer of the convolutions. By negative evidence the areas of mental activity are being shadowed out. By the relations of groups of cerebral cells, the psychical peculiarities of individuals are induced and determined; and in the like relations and similar development of such cell-groups is to be found the explanation of family characteristics. This view is in harmony with the thesis now being generally accepted, that different parts of the brain possess different functions, and the development of a specialised area will be found to correspond to the functional activity of the sense there represented. Further observation may change this from a feasible surmise to an accepted certainty. We already talk of "the path of a psychical reflex act."

In the cerebral cells, too, are contained the inherited residua by which certain actions of a complex character are rendered possible without any individual experience. Thus the chick will balance itself and peck accurately at a crumb on its emergence from its shell. Such complex action is rendered possible in the chick by its inherited residua, while a long period of education is requisite to enable young birds of different genera to perform successfully so complex an action. In the inherited residua are transmitted the properties conferred by descent, and in such residua, together with different groupings, and arrangement or relation of cell-groups, in all probability will be found the explanation of family characteristics of the peculiarities and general resemblances which mark off one family from another; and render possible with one what another can never attain. Probably the musical faculty of one family is accompanied by a corresponding large development of the cell-group, the presence of which makes one person musical, and the absence of which causes another not to know a note. On the primitive size and development of this group of cells depends then the inborn capacity for music which marks one family, and which renders the cultivation of music easy to them, as well as a source of pleasure; while its defective condition in another family causes its members to be indifferent about music, and if any one of them desire to cultivate it, such cultivation will be found to entail much toil and to end in but imperfect success. The comparative development of such cell-groups determines the characteristics of families; which rest on the varying proportion of histological elements in the cortex of the brain. Probably as there is a general physical resemblance in families, so the psychical likeness, the family traits, is associated with certain cell-arrangements which will give the brains of certain families a general resemblance. These histological elements exist and exercise their influence permanently upon the individual. And though circumstances—the pressure of the environment—and the efforts of the individual may modify, and doubtless do modify the cell-groups, and affect their residua, and so the pyschical outcomes, still there remain the family characteristics;—that family resemblance which may fairly be termed the anatomical foundations or groundwork of character. As the development of cell-groups may be furthered by the efforts and pursuits of the individual, so they may be caused to retrograde, until they remain little more than vestigia, exercising a scarcely recognised influence. Thus, Bulwer Lytton, in 2nd chap. of the 3rd book of "The Parisians," says of Vernosta, the retired Florentine singer, "uneducated except in the way of her old profession, and never having troubled herself to read anything but a *libretto*, and the pious books commended to her by her confessor, the artless babble of her talk every now and then flashed out with a quaint humour, lighting up terse fragments of the old Italian wisdom, which had mysteriously embedded themselves in the groundwork of her mind." The mysteriousness of this is no longer so supreme.

"Behind the effects of education, however, are those inherited dispositions which have so much weight in determining the character or temperament of the individual; what his forefathers have felt, thought, and done, though he has never known them, assuredly has some influence upon what he will be inclined to feel, think and do; he has inherited nervous substrata in his convolutions which are ready to take on, at the appropriate stages of his experience in life, the same kind of function which they displayed in his forefathers" (Maudsley).

In time, we will probably have charts or maps of the different cerebral areas of races, as well as of individuals; and in the different cell-groupings, and proportions of cell-groups, find the essential differences which distinguish in capacity and in character, the progressive Aryan from the static Mongol, the Teutonic astronomer from the Chaldean star-gazer. The microscopic investigation of the brain will apparently in time furnish what the phrenologists once thought they had succeeded in doing, and their success was surprising when we remember it was merely the osseous brain-covering they concerned themselves with—viz., the demonstration of the anatomical ground-work of character.

Notes on Current Topics.

The Eye of Man in the Future.

SCIENCE gives us interesting details about what the human eye has been and what it may become. The Vedas of India, which are the most ancient written documents attest that in times the most remote, but still recorded in history, only two colours were known, black and red. A very long time elapsed before the eye arrived at the perception of the colour yellow, and a still longer time before green was distinguished, and it is remarkable that in the most ancient languages the terms which designated yellow insensibly passed to the signification of green. The Greeks had, according to the received opinion now, the perception of colour very well developed, and yet authors of a more recent date assure us that in the time of Alexander Greek painters had for fundamental colours only white, black, red, and yellow. The words to designate blue and violet were wanting to the Greeks in the most ancient times of their history; they called these colours grey and black. It is thus that the colours of the rainbow were only distinguished gradually, and the great Aristotle only knew four of them. It is a well-known fact that when the colours of the prism are photographed there remains outside the limits of the blue and violet in the spectrum a distinct impression, which our eyes do not recognise as a colour. According to physiologists a time will come when the human eye will be perfected so as to discern this colour as well as the others.

Herbalists Again.

WHEN shall we hear the last of the nefarious practices of those "herbalists" who infest the back-slums of most large towns. Quite recently a man named Cornelius Amber, aged 78, described as a herbalist, and living in Archdeacon Lane, was charged with the wilful murder of Ann Gee. The deceased was a married woman, aged 26, living apart from her husband, and having one child of the age of 3 years. She applied to the prisoner to assist her to procure a premature confinement, and he lent his aid, with the result of causing her death in the course of a few days. Her child was suffering from scarlatina and slept with her. When the death of Mrs. Gee occurred a certificate for burial was given in the usual way, attributing her death to scarlatina peritonitis. But within a few days suspicion was aroused, a post-mortem examination was held, and in the result this charge was preferred. Being accused by the friends of the deceased of having caused her death, the prisoner offered them money to hush matters up. The evidence in support of the charge was, as might be expected, somewhat indirect. A visit to the prisoner's house was proved, the post-mortem examination showed the cause of death, and the dying depositions of the deceased, together with the admissions of the prisoner himself, connected him with the case. He admitted having treated the deceased. And among the statements made by her to the witnesses the day before her death was one "that she felt she would die, and that the prisoner had given her death-blow."

The absurd defence was that the wounds discovered at the post-mortem examination were self-inflicted, there being no sufficient evidence to convict the prisoner of having made them. We are, therefore, not surprised that the jury were not long in returning a verdict of guilty, but with a recommendation to mercy on account of his age. We doubt, however, whether his age did not rather forfeit than justify the merciful consideration of his judges, particularly as it appears that this was not the first offence of the same sort of which the prisoner had been guilty. This man was 78 years of age, and if, as is very likely the case, he had been plying his murderous trade long, it is dreadful to think of the crimes and life-long suffering of which he may have been the author. There can be no doubt that the herbalist's shop is the favourite resort of those unfortunate creatures whose misery or degradation induces them to find some means of procuring abortion, and that the abortion procurer often carries on his scandalous trade for a long time before he is found out. It is also to be deplored that the impunity with which these men carry on their practices, even when such practices result in death, is favoured by the laxity with which certificates of death are made out and received by the registrar. We should like to know how, in this case, "a certificate of death was given in the usual way," and who signed the certificate. We all know that the law respecting the signing of death certificates and the burial of the dead is not only imperfect, but, as it is, is often evaded, and the above case affords only one reason why the granting of certificates of burial should be conducted with more care, especially in the more crowded districts of large towns.

Quackery in the Philadelphia Exhibition.

IT seems from the statements contained in the *Philadelphia Medical Reporter*, that the Centennial Exhibition has been made the occasion for the most unblushing, disreputable, and indecent quackery under the sanction and authority of the Commissioners. Large space has been conceded in the so-called Medical Department of the Exhibition to secret quack pills and plasters, which, suitably done up in fancy bottles of attractive form, the public is supposed to interest itself in as in works of art or technology.

The *Philadelphia Reporter* very properly observes that "the exhibition of patent or secret nostrums can in no sense be a proper feature of an industrial display. These bottles and pills, both the ingredients and manufacture of which are concealed, give no incentive to culture in any respect; they teach nothing; the exhibit cannot possibly benefit anybody but the proprietor; and it does this at the expense of the more ignorant class of visitors, and of the managers of the exhibition, on whose intelligence and sense of propriety it becomes a conspicuous and lamentable commentary."

The admiration of Brother Jonathan for the earning of money by any method, and for those who have the 'cuteness to succeed in the accumulation of dollars has induced him to encourage the quack pill trades of the States by all the publicity in his power to afford.

A concession has been granted one notorious Eastern patent medicine man to put up and devote a whole building to the display of his nostrums, and in the main building prominent cases are filled with these certificates of American ignorance and gullibility. Circulars and handbills are prominently laid out for the crowd to pick up, and thus the traffic which all honest physicians and pharmaceutists are striving to check is fostered and countenanced by the very men who should have represented the foremost culture and best interests of the time.

Nor does any discretion appear to have been used. Two circulars are extensively distributed both from rather large exhibitors. One of these has sixteen pages extolling an elixir "for preserving the beauty and restoring the health of women, and maintaining the strength and virility of men!" It is filled with certificates and positive promises to cure sterility, uterine congestion, puerperal convulsions (!), and, of course, impotence and spermatorrhœa.

The second circular is in regard to the medical value of a certain extract. It commences with the following profound remark: "It is well known that the source of all diseases is in the impurity of the blood and in the crassitude of the bodily humours!" And this is the stuff the International Centennial Exhibition of 1876 permits to be supplied for the education and culture of its visitors.

Pauper Dwellings and their Inspection in London.

Last week the coroner held two inquests at Holborn concerning the death of two children. The former lived at 12 Little Gray's-inn Lane, and the latter at 29 Lacy-Buildings, Holborn. The relieving-officer called attention to the state of these houses. They were worse than pigstyes; in fact, pigs would not be put in such places. He thought that it was a shame that such places should be allowed to exist. The law compelled him to go into any house where he was called. During the nine years that he had been officer in this parish, he had had small-pox twice and fever three times. The jury returned verdicts of "Deaths from Natural Causes," and added that the houses were unfit for human habitation.

A Novel Method of Medical Touting.

A correspondent of the *Students' Journal* writes that in Liverpool, there resides a practitioner possessing excellent qualifications, little ambition, and good taste, who during the winter months, for the benefit of humanity (including of course himself), occupies his time on Sunday afternoons in lecturing to illiterate crowds upon medical topics, and permeating the proceedings with religious elements in the shape of Sankey's hymns and Moody's prayers.

On a Sabbath afternoon, at the conclusion of his lecture, our hero might be seen with a bundle of diplomas and certificates, calling aloud upon his audience to come and inspect the rewards of his industry. On another occasion, when *scientifically* treating the subject of "Pain Killers," he benevolently invited any who were in pain to come on to the platform, and having taken them behind a screen, graciously administered to each an injection of morphia. He also lectures on "The Contagious Diseases Acts," and holds forth to "men only" on syphilis; sells his previous lectures at sixpence each to the meeting, and places the syphilitic one in a sealed packet, and forbids its perusal by females.

The writer of the foregoing if he be in a position to substantiate the accuracy of the facts, stated, should not hesitate to give the name of the person referred to. We should then be able to satisfy ourselves as to the "Excellent Qualifications," and the responsibility of such conduct would be upon the college who granted them as much as upon the possessor of them.

Election of Registrar of the General Medical Council.

The expected election to the office of Registrar, vacant by the resignation of Dr. Hawkins, is announced to be made by the Executive Committee of the Council in October next. The salary is £500 a year.

Post-mortem Test of Respiration in the Infant.

In *Virchow's Archiv.*, Dr. Erman, of Hamburgh, relates the case of a woman who was delivered of three seven and a-half months children, two coming into the world living, and the third being dead-born. Both these children cried loudly while being washed, their cries being heard in another room at some distance off. They both died half an hour after they were born. At the autopsy it was found that the whole of the lung of the one child sank in water, even when cut into small pieces; and the lung of the other did the same, except as regards a very small portion of the edge of one of the lungs. The lungs in both were undistended, dense, and of a bluish colour.

The Vivisection Question.

Some of the news respecting the vivisection question is of a very antagonistic nature. Thus we are informed, almost in the same breath, of a meeting in Ireland, the object of which is to support the action which has been taken in the matter by the profession, and of another meeting in Willis's Rooms, the object of which is the formation of an "International Association for the Total Suppression of Vivisection."

With regard to the meeting in Ireland, we are glad to see that the Council of the Royal College of Surgeons of that country has adopted resolutions in accordance with the general views of the profession already published in our columns.

But with respect to the exact nature of the resolutions passed at the "large and influential meeting" held in Willis's Rooms we are not so well informed. No doubt they are calculated to strike a good deal of terror into the ranks of the vivisectionists and their friends, and of course they used the usual stock means of getting up a society, raised the parrot-cry customary on such occasions, and were "unanimous in opinions that the feeling of the country is strongly in favour of total abolition, and that there is absolute need for such a society!" There are many animals which, however low they may be in the zoological scale, however repugnant they may be to mankind, can, nevertheless, at times do much mischief, especially if irritated or unnecessarily interfered with. And very probably these societies of mushroom-like growth will, for a time throw many obstacles in the way of adopting those methods of investigation which a small body of respectable men has thought advisable to practise in the interests of science. Take no notice of such societies, and they and their cause will soon die a natural death, for in science, as in all other things, right will no doubt prevail in the end.

The War Hospitals.

The latest telegrams from correspondents at the seat of war in Turkey, Servia, &c., go to prove that the atrocities said to have been perpetrated on the wounded of both sides were much exaggerated, and in some cases absolutely untrue. The hospital accommodation, however, is terribly insufficient, and the medical and nursing departments, especially in the Servian army, of the most wretched description. The sufferings of the wounded are in consequence much increased, hundreds of cases lying for days untended, until Death has in many instances mercifully relieved their agonies. There appears to be an insurmountable dread of amputation amongst the Servians, who are generally men of splendid physique and great powers of endurance; they will rather die than submit to an operation. This characteristic determination was strikingly shown last week, when, after an engagement, forty amputations were deemed necessary, thirty six of the number electing to die rather than live on minus an arm or a leg. British surgeons are much wanted, and medical stores, especially bandages, lint, antiseptic dressings, and stretchers are urgently required. The war has at present resulted in nothing but minor engagements; should it last, which many in a position to judge consider highly probable, and heavy battles ensue, the position of the wounded will be terribly aggravated. Civilised Europe joins in the hope that its duration will be very short; in the interim there is unfortunately plenty of scope for the younger members of our profession bent on military surgery.

Adulteration Prosecutions.

Several interesting proceedings against adulterators are reported in England. At Dunster, in Devonshire, a shopkeeper, was prosecuted for selling pepper containing 10 per cent. of starch. Evidence was produced that the presence of the starch arose from the pepper having been ground in a mill in which beans had been previously ground. The defendant drew the attention of the bench to the fifth section of the Adulteration Act, 1875, by which it was provided that no person should be liable to be convicted if he proved absence of knowledge of the article being adulterated; but the bench expressed an opinion that although the pepper had not been wilfully adulterated, the presence of the starch could have been avoided. The fine was a nominal one, 6d., and costs. The fine and the costs, £4, were paid.

The manager of the Balham Co-operative Stores was summoned for selling to the prejudice of the purchaser arrowroot which was adulterated with tapioca. A certificate was produced from Dr. Muter, the analyst of the local board of works, stating that the sample was adulterated with 50 per cent. of tapioca. The inspector appointed under the Act said that tapioca was sold at 4d. per pound. He paid 1s. for half a pound of arrowroot. Mr. Ingham remarked that the defendant made 6d. profit upon every half pound of arrowroot. The defendant offered no defence. He wished to absolve the stores from all blame. He sold the article under a guarantee, and it was bought under a guarantee. Mr. Ingham said he had no doubt the defendant believed he had got a genuine article. He fined him 5s. and 23s. costs, which he could recover from the person who supplied him with it.

William Brown, spirit merchant, was charged at Greenock with having sold a bottle of whisky which was not of the nature, substance, or quality demanded by the purchaser. The report from Somerset House stated that the sample of whisky had been adulterated with 427 grains of hydrated sulphuric acid in the imperial gallon. The defendant stated that he never had vitriol in his shop. Never had anything called sulphuric acid. The sheriff, in giving judgment, remarked that the defendant was not charged with having adulterated the whisky, but he was charged with having sold it in an adulterated state, and there was little doubt that the prosecution had succeeded in proving that he had done what he was charged with. He considered it a case of gross carelessness, and would pass sentence of £5 with £5 expenses.

At a Bradford Police Court, a hair-dresser was summoned on a charge of selling an article called ginger ale which was not of the quality demanded by the purchaser. The case was that though the beverage was innocuous and palatable it was not "ale" and should not have been sold under that name, and the Bench dismissed the case.

As is well known we have advocated repeatedly, and in the strongest terms the suppression of adulteration and the punishment of trade rogueries; and being thus anxious to encourage honest trading and fair business competition, we very much regret to observe in two of these cases a disposition on the part of inspectors and analysts to ride the hobby to death, and enforce against shopkeepers the utmost letter of the law. Neither the pepper case nor the ginger ale case were legitimate occasions for prosecution, for in neither was there any intention to defraud, nor was anyone misled as to the nature of the articles purchased. No one who drinks "ginger ale" confounds it with the fermented alcoholic beverage, and, therefore, no one is wronged by the sale, and the magistrates showed their astuteness in dismissing the case. The commonsense test of an adulteration is the deception of the public. In the "milk of sulphur" or "citrate of magnesia" cases the purchaser *is* deceived. In the "ginger ale" case he is not. Forced by the law to comply with the principle of honesty, the manufacturers of cocoa, mustard, &c. have been obliged to state upon their wares something of real nature of their wares, and they have exercised their ingenuity in constructing labels to come just within the limits of the law, and, at the same time to give the consumer as little information as possible. In illustration of this fact, a correspondence has taken place between the "National Chamber of Trade" and the Local Government Board, arising out of the prosecution of two grocers for selling cocoa containing cocoa-butter, cane-sugar, and sago-starch. The fact was proved that the cocoa was labelled as a compound. The Bench, notwithstanding, decided that the defendents had made themselves liable for not stating this to the purchaser when the sale was effected, and fined them 10s. 6d. each, and costs.

The label on the package of cocoa was as follows :—

SOLUBLE
COCOA,
Manufactured by
TAYLOR BROTHERS,
LONDON.

This admixture contains no injurious ingredient.
38 & 39 Vic., c. 63.

The Local Government Board was requested to state "whether the above label is a sufficient notice to the purchaser that the article is a compound."

The following is the reply :—

"The Board has no information as to the grounds on which the decision of the magistrates was based, but they think that the label, of which you have forwarded a copy, might be framed in more distinct terms.

"The Statute 38 and 39 Vic., cap. 63, sec. 8, requires that the vendor of any compound article of food shall supply to the person receiving it a notice "by a label distinctly and legibly written or printed on, or with the article, to the effect that the same is mixed.

"In this particular case, for example, such words as the following might be used on the label : 'This is an admixture, but contains no ingredient injurious to health.'"

Impure Ice.

We cannot help saying that in our opinion a considerabe amount of exaggeration has been imported into the story of an epidemic from the use of impure ice. It must have been ice known in the trade as "rough-ice," taken from ponds "horribly foul," and if so, impurities can be readily seen and detected without a magnifying glass. Ordinary organic matter sinks to the bottom of all lakes and rivers the moment the temperature of the water falls below 32° Fahr. The tale as told by our contemporary the *Lancet* deserves attention only so much as applies to the negligence or malicious carelessness of the servants of the hotel, the inmates of which were, it is said, suddenly attacked by serious disorder, marked by giddiness, nausea, vomiting, &c. The story is that it at last attracted attention, and that an analysis of the water derived from the ice used in the hotel was made, and it was found to be "horribly foul." The pond from which it had been gathered was examined, and it presented "a homogeneous mass of marsh mud and decomposing sawdust." On this particular ice being disused the epidemic came to an end. Probably some people are under the impression that ice purifies itself in the process of freezing ; but this case clearly proves—what is asserted in the American report on the subject—that such a belief is utterly erroneous, and it must be wrong to use ice taken from ponds that are unfit for drinking purposes. The *Lancet* comes to the somewhat alarming conclusion that "tons of ice are consumed daily in London which have been obtained from ponds the water of which no one would think of drinking." Thereupon the *Globe* says, "Here is a new field for the operations of public analysts. These officials periodically alarm us by terrific descriptions of the tea, sugar, and pickles in common use ; and we are only too familiar with their vivid pictures of the living organisms with which the water companies are said to supply us. Their labours in these directions will be frustrated if the public are to be poisoned by a pleasure which every one has hitherto imagined to be as harmless as it is delightful."

Royal College of Surgeons of England.

At the meeting of the Council of the College last week Mr. Prescott Hewett was elected President ; Mr. Birkett and Mr. Simon Vice-Presidents. Sir James Paget in retiring leaves some heavy work for his successors, but he leaves it in good hands. The new President of the College has never yet held an appointment or office without devoting all his energies to the work which it entailed, or we may add without realising that amount of success which ever accompanies well-directed ability. Sir James Paget will replace Mr. Quain as representative of the College of Surgeons in the General Medical Council, an appointment which will give general satisfaction.

Dr. Sieveking and Dr. Bristowe were appointed Examiners in Medicine ; Mr. Carter, Professor of Surgery ; Mr. Flower and Mr. Parker, Professors of Comparative Anatomy ; Mr. Erasmus Wilson, Professor of Dermatology ; and Mr. Lowne, Professor of Anatomy and Physiology.

Subcutaneous Osteotomy.

The success which has attended division of the femur for deformity with chisel and mallet certainly warrants repetition. On July the 15th Mr. Maunder operated upon two patients, and showed others who had been benefited by the operation. The gathering of strangers in the theatre showed that subcutaneous osteotomy is exciting some interest in the surgical world.

Longevity in Ireland.

As many as 20 of the persons whose deaths were registered in Ireland in the first quarter of the present year are described as centenarians. There are three among them registered as 106 years old, one 109, one woman 110, and two men 111 years of age. The local registrars do not vouch for the truth of the statements of age. The registrar of Dungiven, Londonderry, however, after recording the death of a person returned as aged 102 years, adds—"Which from minute inquiries is believed to be accurate." The registrar of Tallow, Lismore, returning one death at the age of 111, says—"This man was married 1798, the year of the Rebellion, and was then 33 years old." The other death at 111 is recorded at Castleblayney, and the registrar says—"Informant said he could bring proof that the deceased was born in 1765, and it seems death took him by surprise in 1876, as he fully expected to reach his father's age, said to have been 115."

Society for Relief of Widows and Orphans of Medical Men.

A Quarterly Court of the Directors of this Society, under the presidency of Sir George Burrows, was held, by the kind permission of the Royal Medical Chirurgical Society, in their rooms, Berners Street, on Wednesday last. The sum of £1,271 10s. was voted to sixty widows and twelve children, divided according to the exigency of each case. The expenses of the quarter amounted to £44. Two fresh applications for assistance were admitted. Two new members were elected. The directors, acting under a special bye-law, recommended that at the next general meeting in October a grant of £20 should be made to the daughter of a late eminent physician (formerly a member of the Society) in great distress from loss of income and suffering from incurable diseases.

Statistics and Intemperance.

From the report which has just been issued by Her Majesty's Commissioners of Customs our attention is directed to the curious fact that though the year 1875 was not a prosperous one for commerce, for trade, or for our national harvest, yet the revenue from Customs showed a more than usual increase. "It has always," observe the Commissioners, "been held by the best authorities on questions relating to incidence of taxation that the bulk of the revenue from duties of Customs, of which almost the whole is derived from tobacco, spirits, tea, dried fruit, coffee, and cocoa, is paid by that portion of the population which is dependent upon weekly wages, comprising, as it does, the great majority; for wine, consumed principally by a richer class, contributes less than nine per cent. of the whole. Accepting this opinion as to the incidence of Customs duties, it seems difficult to reconcile the fact that these duties have increased at the rate of 5·3 per cent. during the past year, with a state of trade so exceptionally bad as has been above described."

Now among these different articles the consumption of which increased at such a rapid rate, spirits of all kinds form a very prominent item, and we are informed that the augmented consumption of spirits was as much as 72 per cent. No doubt the total abstainers and the temperance societies will turn this fact to account, and erroneously conclude that that alone shows how intemperance is spreading among the lower classes. Even those who are not inclined to form extreme opinions on the intemperance question have concluded from the above facts that the year 1875 was not a good one for the working classes, but that so far from stinting themselves at the public-houses, they must have determined to counteract the gloom around them by drowning dull care in the sparkling bowl." But the fact is, last year was by no means an unprosperous one as respects the vast majority of unskilled labourers, as may be shown by a closer examination of this report, and by the facts respecting the decrease of pauperism to which the Registrar-General lately drew attention. Unfortunately for the inference which would connect the increased consumption of spirits with a corresponding increase in intemperance, it will be noticed that there was alsoa corresponding increase in the consumption of various articles of food, all of which must be accounted for either by increase of population, or by the increased prosperity of the working classes. Allowance, however, is made for increase of population, and therefore it follows that when spirit is only one of many articles the consumption of which have been on the increase, the circumstance must arise not from the more intemperate habits of the consumers, but from large numbers being able, either through increase of wages or economy, to provide themselves with luxuries which they are obliged in less prosperous times to do more orless without.

The Case of Dr. Deville.

We recently commented upon the summary dismissal of Dr. Deville from his post as Medical Officer of Health for Harrogate, for declining to stoop to the dictatorial interference of the so-called Sanitary Board of that town. We are glad to find that Dr. Deville has been supported in his action not only by his *confrères* of the neighbourhood, but also by the leading inhabitants, a numerously signed memorial having been forwarded to the Local Government Board protesting against the vindictive and unjust action of the Harrogate Commissioners.

Mr. Prescott Hewett is the newly-elected President of the Royal College of Surgeons of England.

The Clothworkers' Company have promised a yearly donation of a hundred guineas to the London Hospital.

The Earl of Leicester has subscribed £5,000 towards the £35,000 required for the improvement and enlargement of the Norfolk and Norwich Hospital.

H.R.H. the Prince of Wales has enriched the Museum of the Royal College of Surgeons of England by the presentation of some skulls and skeletons of animals shot whilst in India.

On Saturday the excessive heat of the past fortnight attained its maximum: at the Wimbledon Camp 143 degrees were registered, being the highest on record. On Sunday in the London parks 135 degrees in the sun, and 92 in the shade were reached.

At the last meeting of the Croydon Board of Guardians it was resolved to furnish from the workhouse quinine and cod-liver oil to the medical officers of the union districts, with a view to diminish the consumption of wine and spirits prescribed for the sick poor.

We mentioned in a recent number that Mr. Quain, the representative of the College of Surgeons, England, on the Medical Council, intended resigning that position. At the last meeting of the Council of the College, Sir James Paget was elected to the vacant post, *vice* Quain.

Sir James Lomax Bardsley, M.D., F.R.C.P., who died last week, was the author of "Diabetes" and "Hydrophobia," articles which appeared in the "Cyclopædia of the Practice of Medicine;" also of a pamphlet on "Hospital Facts and Observations." Deceased was Consulting Physician to the Manchester Royal Infirmary and a Justice of Peace for Lancashire.

A **report** by Mr. T. F. Evans on the metalliferous mines in Wales, which is referred to in *Iron*, discloses conditions affecting the persons labouring in them which deserve attention. Mr. Evans finds the average age at death of the slate miners at Festiniog to be thirty-eight years; excluding accidents it is below forty-one years, or twenty-six years below the average age of death of males not employed at the mines. This also occurs among a class of workmen physically and morally superior to the average, and who receive wages high enough to secure every domestic comfort, whilst they are generally temperate in their habits, and spend their leisure "principally in religious exercises and the cultivation of literature and music."

◆

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE VIVISECTION BILL.

The Royal College of Physicians have drawn up the following petition to the House of Lords :—

"That your petitioners view with deep concern a Bill now before your Lordships, entitled, 'An Act to prevent Cruel Experiments on Animals,' for medical and physiological purposes, believing that if passed into law, with its present provisions, it will seriously interfere with the advancement of science, the relief of suffering in man and animals, and the welfare of the public.

"That your Petitioners, fully assured of the incalculable benefits to humanity which have been derived from investigations into the laws of life and the nature, spread, and control of disease, and the action of poisons, whether taken accidentally or given intentionally, through the aid of experiments on living animals, from the time of their most illustrious associate William Harvey to the present day, cannot but view with serious apprehension those provisions of the said Bill which threaten to prevent the pursuit, in this country, of those studies with which the best interests of mankind are vitally connected.

"1. Your petitioners would especially pray that the title and preamble of the said Bill may be so amended as not to cast on physiologists and teachers of medical science an unjust and disproved charge of cruelty.

"2. That the limits of research, by experiments, may not exclude any investigations having for their object the acquirement of further knowledge of facts and laws relating to health and disease.

"3. That experiments of research in non-registered places may be permitted on a special certificate granted to persons of known character and position.

"4. That the limitation which the Bill imposes as to the animals which may be made the subjects of experiments may be omitted, inasmuch as domestic carnivorous animals are necessary for many purposes of experimental investigation.

"5. That the provision in Clause 13 apply only to non-registered places.

"Your petitioners, in presenting these requests, are influenced by those sentiments of humanity of which this nation justly boasts, and which have always been, and ever must be, dear to those whose daily duty it is to obviate and alleviate suffering and preserve life.

"And your petitioners will ever pray."

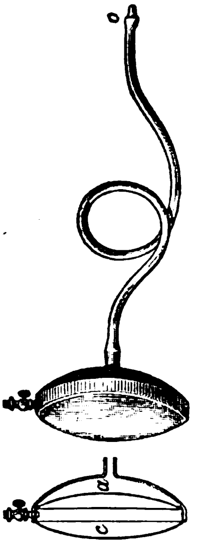
New Inventions.

NEW FORM OF STETHOSCOPE.

Mr. Yeates, of Dublin, has recently introduced to the profession in that city a new form of stethoscope worthy of notice, not only for its accuracy but because it provides the only method of auscultation which enables several observers to hear chest-sounds at the same instant. The adaptation of acoustic principles to this purpose is due to Professor König, and the instrument is figured and described in the latest edition of Ganot's Physics. In the margin we give an illlustration.



Two sheets of caoutchouc, C and A, are fixed to the circular edge of a hollow metal hemisphere; the edge is provided with a stopcock, so that the plates can be inflated, and then present the appearance of a double convex lens as represented in section in Fig. 1. To a tubulure on the hemisphere is fixed a caoutchouc tube terminated by horn or ivory, O, which is placed in the ear. When the membrane of the stethoscope is applied to the chest of a sick person, the beating of the heart and the sounds of respiration are transmitted to the air in the chamber, C, A, and from thence to the ear by means of the flexible tube. If several tubes are fixed to the instrument, as many observers may simultaneously auscultate the same patient; and as many as six persons may thus observe not only the same character of sound, but actually the identical sound.

NOTES FROM OUR AMERICAN EXCHANGES.

Chronic Pleuritis.

Dr. W. T. Chandler, Cambellsville, Ky. (*Philadelphia Med. and Surg. Reporter*), believes that chronic pleuritis is a disease frequently overlooked, or mistaken for phthisis pulmonalis, in the diagnosis and treatment of chest affections. He cites in proof of this assertion, some interesting cases which have fallen under his notice in practice. The following history of one of his patients will serve as an example:—A young married woman, aged 22 years, shortly after her confinement, was seized with symptoms which her medical attendant pronounced to be those of acute pneumonia, and which, from their persistent nature, he believed to be phthisical in their nature. Six months later, so much was the patient reduced by hectic fever, cough, &c., he pronounced her incurably consumptive, and sent her into hospital to die.

On entrance into hospital, when examined by Dr. Chandler, the following symptoms were observed:—Great emaciation. Loss of appetite. Harassing cough. Hurried respiration. Pulse 125, quick and feeble. Respiratory sounds heard only in one lung. The right side expanded and contracted with each act of respiration; the left remained perfectly stationary. There was an entire absence of vocal and respiratory fremitus in the left side. The cardiac impulse was seen and felt deflected to the right of the sternum. There was decided bulging of the left side, which, on measurement, was found to be two inches larger than the right; the intercostal spaces presented the characteristic prominence in cases of pleuritic effusion. Percussion revealed dulness over the whole of the left side anteriorly and posteriorly, with increased resonance on the right. The vesicular respiratory murmur was absent throughout the entire left lung, but in the right, compensatory respiration was well marked. The case being evidently one of pleuritic effusion, the next step was to determine the nature of the fluid present. The hectic fever, emaciation, night-sweats, and prostration favoured the idea that empyema existed. This was confirmed by aspiration, when 43 ounces of fœtid pus were drawn off. The puncture was made between the eighth and ninth ribs, about six inches anterior to the spine. This puncture was subsequently enlarged, by the introduction of a bistoury, for the purpose of inserting a drainage tube, through which the pleural cavity was daily washed out with a weak solution of carbolic acid; a counter opening was made between the tenth and eleventh ribs, to facilitate the escape of the disinfecting fluid and the discharge of pus. The patient was sustained by the free use of brandy or whiskey, quinine, and the muriate tincture of iron.

After the second week, improvement became marked; recovery was complete at the end of the third month. On removal of the drainage tubes, at the end of three months, the left lung had completely recovered its normal distension, and the pleural cavity was obliterated by adhesions between the pulmonary and costal pleura. At the end of seven months, on examination, there was nothing to indicate the previous existence of pleural or pulmonary trouble.

Uterus Subseptus.

W. L. **Richardson**, M.D., Visiting Physician to the Boston Lying-in Hospital (*The Boston Med. and Surgical Journal*), reports an interesting case of uterus subseptus occurring in the case of a young married woman, æt. 25, four years married, and the mother of three children. She had menstruated regularly, except when interrupted by the pregnant condition, since she was thirteen years of age; the menstrual periods were always ushered in by severe pain, and usually lasted three days. Nothing abnormal occurred in the course of her confinements, except in the first, when a smart dash of hæmorrhage attended the commencing pains of labour. The condition of the uterus were diagnosed, but she would not permit a verifying examination to be made. She came under Dr. Richardson's care for constipation and dysmenorrhœa. An examination showed the vagina to be normal. At its upper extremity two ora could be distinctly seen; the right appearing, like the os of any woman who had borne children, slightly patulous, round, and with an irregular slit at one side; the left was like that of a virgin. Between the two ora was a band of normal tissue measuring about one-third of an inch in width. The sound could be readily introduced into the right os, and by it the length of the uterus was found to be two inches and a-half. On bending the sound slightly, it could be easily introduced into the left os. Sounds introduced at the same time through each os were found to have passed into the same cavity. By sharply bending the end of the sound, it could very readily be passed into one os and out at the other. There was no appearance of an inflammatory action having existed at any previous time in the region of the uterus; nor could the patient give any account of the history of any previous uterine disease. A digital examination made *per rectum* and *per vagina* detected nothing abnormal in the size or position of the uterus.

The case is interesting, as showing that a double os does not necessarily indicate any abnormal conditioneof the uterine cavity above. As a point of practical interest to the accoucheur, the existance of a double os might give rise to an error in judging of the stage at which labour had arrived at any given time. If the physician should make his examination hastily and carelessly, and chance to detect the undilated os alone, not recognising the existence of the second, whose dilatation was more or less completed, he would be liable to fall into the error committed in the case reported; the medical man in attendance during the first confinement, on examining, felt the left, or undilated os, alone, and gave it as his opinion that labour had not as yet commenced, and would not probably begin for some time. The truth was, the first stage was nearly completed, and the child was born soon after the examination was made, and the opinion given.

Cephalic Version in Arm Presentation.

Dr. L. **Hatchett** (*Medical and Surgical Reporter*, 1876) reports a successful case in which the above operation was performed. Pains had been felt forty-eight hours, and the liquor amnii discharged twenty-four hours, previous to the doctor's being asked to see the patient, a young Swedish lady in her third confinement. The maternal passages were so swollen, inflamed, and exquisitely tender that chloroform was necessary before an examination could be made. The left arm of the child was found low down in the vagina, and its body presented transversely in the uterus in the dorso-anterior position, the head being directed to the right. Dr. Hatchett introduced his hand into the womb, carrying the arm of the child with it. He then made pressure upon the pelvis of the child, directing it towards the fundus of the womb, making at the same time counter-pressure with his right hand on the right abdominal surface of the mother. The head came down without any difficulty. Case terminated rapidly by delivery of a fine healthy child weighing 9 lbs. It was partially asphyxiated at birth, but in the course of half-an-hour breathed naturally. There was severe post-partem hæmorrhage, but the mother made a good recovery. Owing to the mortality attendant upon podalic version, Dr. Hatchett considers cephalic version preferable where it can be accomplishedd. It is certainly a measure to be borne in mind in dealing with cases similar to that reported.

Treatment of Pruritus.

Dr. N. L. **Folsom** (*Medical and Surgical Reporter*) reports the case of a fat woman, aged sixty, who suffered from a most obstinate and severe attack of pruritus, affecting the vulva, clitoris, and mons Veneris. It so overcame her that she was nearly helpless. She was actively treated, both externally and internally, for several months, but every remedy tried failed to give relief. Finally, essence of peppermint was applied locally to the itching parts with great success. Relief was immediate, and the occasional use of the remedy kept her happy.

Gestation extending to Three Hundred and Six Days.

Dr. Thos. T. **Graves**, Lynn., Mass. (*The Boston Med. and Surgical Journal.*) reports a well-established case of gestation extending to 306 days, in the case of a young lady, a Miss E., aged seventeen years, married to a Mr. H., the mate of a vessel, June 16th, 1874. She lived with her husband until he sailed, April 8th, 1875. Three days before he left home his wife ceased to menstruate, and had intercourse each of the two nights following. Two or three weeks after he sailed Dr. Graves was called in, as she felt indisposed, and complained of nausea. At the end of nine months she had slight pains, but they passed over without the induction of labour. On the 306th day, after a labour of four hours' duration, she gave birth to a healthy male child, weighing 10½ lbs. The child was very fa long finger nails, and plenty of hair. It was very vigorous from birth. The well-ascertained facts of this case make it very interesting, as establishing the possibility of such a prolonged gestation. By the Code Napoleon, 300 days are all that are allowed as the extreme limit of the pregnant condition. In this case, had the lady been amenable to that code, a divorce might be procured, which would have been unjust, and, as Dr. Graves pertinently remarks, if unjust in this case, why not in others of a similar character, should they occur?

THE PRURITUS OF PREGNANCY.

PROFESSOR J. R. BLACK, M.D., writes in the Cincinnati *Lancet and Observer* (*Med. and Surg. Reporter*, May 13th, 1876,) in favour of the use of hydrate of chloral as a topical remedy in the pruritus of pregnancy. He gives the particulars of three cases in which its application was most successful, the relief being prompt, decided, and permanent. The following is the formula which he is accustomed to prescribe—

℞ Chloral hydrate, ʒiij.
Aqua, ʒiv. M

The parts affected to be sponged with the solution.

One application gives almost immediate relief. In one case severe smarting was felt, but this soon passed off. The use of the hydrate of chloral is equally serviceable in the case of the itching attendant upon urticaria.

Correspondence.

THE NEW PUBLIC HEALTH BILL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—The introduction of another Public Health Bill seems to invite discussion on the working of that one which was passed in 1874. The codification of existing sanitary laws proposed by Sir M. Beach is indeed an absolute necessity. The present Bill, however, does not stop at this, but introduces some changes of detail which will be found of great value. It is true that scarcely two years have elapsed since the introduction of the last Public Health Bill, yet sufficient experience of its shortcomings has already been attained to enable a definite opinion to be formed as to its value. I am satisfied that that Act has been allowed to remain in the great majority of cases as more or less of a dead letter. I give this not as the result of my own experience only, but as that also of many medical friends scattered throughout the kingdom. The causes that have led to this are various. The bodies to whom its administration was entrusted were already provided with occupation sufficient for all their available time and energies. Public opinion, too, was, and is not, educated enough to sufficiently appreciate the value of sanitation. This cause is one, however, with which no legislation can deal; time and increased knowledge must alone supply the remedy. The withdrawal of sanitary authority from municipal bodies of towns under 6,000 has been also one of the leading causes of the failure of the Act. This did not form part of the Government Bill, but was introduced into it on the suggestion of Mr. Errington. The results of the change have been most unfortunate; the boards of guardians neither have the same time nor the same local interest nor local knowledge that the small municipalities brought to the management of sanitary matters. The provisions of the Common Lodging-Houses Act, for instance, have been painfully neglected since their execution was taken out of the hands of the local commissioners. The leading idea of those who stripped the smaller municipal bodies of their sanitary powers was that the Poor-law boards would display a greater independence in dealing with abuses. I fear that my experience would not confirm that opinion. A great deal has been lost; and if we except that the Local Government Board has had fewer authorities to rule over, nothing whatever has been gained.

The fact that there is an undeniable conflict between the duty of the sanitary officer and the interest of the practising physician has also lent its share to the failure of the Act; greater far, however, than any of these, has been the influence for evil wrought by nominal salaries, and the absence of any superintending official in each union. Dr. Grimshaw hit the great blot when he laid such stress on this very point, in his evidence before the Local Government Committee. The absense of anything like inspection of districts has been also productive of evil—parties aggrieved and grown weary of interminable correspondence with the Local Government Board have had nothing left to them but to continue to suffer in silence. The Bill at present before Parliament will scarcely pass this session; there seems, therefore, likely to be time enough for ventilating suggestions for its future improvement.

Analysing the present Bill, I would suggest that Clause 6 should give power to the Local Government Board to disjoin towns under 6,000, and convert them into urban sanitary authorities, on application made and cause shown. Clause 10 should give the Local Government Board exclusive power to fix salaries, lessen the number of sub-officers, give discretion to the Local Government Board to prohibit private practice by superintending officers, and appoint all superintending sanitary officers henceforth by competion, examination, and after special training, give power to unite at discretion of the Local Government Board more than one union under superintending officer. Where sanitary authority would make no order at two successive meetings the superintendent should have power "proprio motu" to send the case to the tribunal of first instance. This would effectually meet the difficulty caused by Boards hearing whole sheaves of reports read and taking no notice thereof. Clause 138 would be rendered more valuable in the working if the Local Government Board provided the local authorities with an uniform design for ambulance carriages, constructed on the most improved principles, and insisted on providing themselves with them. Those at present in use in most places are of the rudest construction. Clause 139. The authorities appear to be too timid in grappling with the prejudices which oppose the compulsory removal of contagious cases to hospital. These prejudices are neither so wide-spread nor so deep-seated as are believed. Powers of compulsory removal should be given, though they might be used tentatively. The want of such a provision as this every other day leads to extension of disease, loss of life, and increased burthens on the ratepayers. In a neighbouring town where fever largely prevailed I know of at least one case where the death of the parent and consequent pauperism of the entire family have been the direct result of the want of such a clause. This individual death I am satisfied is not the only loss. There are present forty cases of fever in the Cashel Fever Hospital, not ten of which I believe I should have had if early rigid isolation had been practicable. A converse fact in proof of the value of compulsory removal may not be out of place. In '72 fever largely prevailed in this city, and spread from thence to the large union workhouse. The instant an inmate of the latter made the slightest complaint he was compulsorily removed to isolated wards for individual patients, and from these he was transferred to the contagious or non-contagious wards, as the disease declared itself. The result was the early and complete extirpation of the disease. Clause 140 should be enlarged so as to give sanitary authorities power to close public schools when occasion might demand. I met with a notable proof of the necessity for this. Clause 203. Superintending officer should be responsible for thorough inspection of district, subject, of course, to supervision of the Local Government Board's officer. Clause 206. Local Government Board ought to get power under this clause where a board of guardians ask for it, or is dissolved for continued contumacy, to create a new and permanent sanitary authority out of different materials altogether, such new authority to be composed partly of local members selected by the Local Government Board, partly of others selected by the different municipal bodies of the district in which the dissolved board might be situate. Had the working of the Sanitary Act been originally committed to the charge of boards, elected partly by boards of guardians and partly of municipal bodies, I incline to think the outcome of the Act of 1874 would have been quite different from what it is. No provision is made in the present Bill for providing for those difficulties which are sure to arise in connection with the all-important subject of the thorough registration of sickness. Parliament must by this time be rather wearied of incessant tinkering with sanitary legislation. For that reason it might be less difficult to make in the present measure those additional changes which existing experience may suggest than seek for further modifications in a few years hence.

Yours truly
THOMAS LAFFAN, L.K.Q.C.P., M.R.C.S.E.

ALLEGED ABUSE OF LUNATIC ASYLUMS.

In the House of Commons last week,

The Lord Advocate, replying to Mr. Ramsay's inquiry respecting private lunatic asylums being used as refuges for bankrupts and for ministers to avoid trial by their presbyteries, said that, in the cases referred to, the proceedings of the bankruptcy contained no allusion to anything discreditable on the part of the bankrupt. As to the minister specially referred to, he still remained in the asylum, and there was no doubt that he was properly placed under restraint.

Mr. Dillwyn afterwards rose to call attention to the operation of the existing laws relating to the committal and custody of lunatics, and to move—"That, in the opinion of this House, those laws do not afford sufficient safeguards against illegal incarceration and the maltreatment of lunatic patients." He referred to the great increase in the number of lunatics throughout the country, which had led to the provision of county asylums and other accommodation for their reception; and he ascribed that increase, in a great measure, to the lax administration of the law. He thought that the law officers or some competent independent authority who would not be under any suspicion of favouritism ought to prosecute all cases of violation of the lunacy law, and to require that no person should be placed in a lunatic asylum without the warrant of some public authority. He further proposed that all private lunatic asylums should be abolished, and that all such places of confinement should be public institutions.

The House was counted out before the resolution could be passed.

Medical News.

Royal College of Surgeons of England.—The following candidates having passed the required examination received the diploma in Dental Surgery, at a meeting of the Board of Examiners on the 29th ult.:—

Bateman, George W., Elgin-crescent; Birt, Stephen, Leamington, Warwick; Brown, Richard, Tavistock, Devon; Carter, Thomas S., Leeds; Fairbrother, Horace J. L., Stockwell; Furber, Alfred W., Kentish-town; Marriott, George H., Albion-street; Mason, Henry B., Exeter; Roberts, Thomas A., London; Small, Moreton A., Marylebone-road; Stevens, Lewis W., Swansea; Weiss, Felix H., Montague-place; Willis, William F. Blackheath.

University of Dublin.—The following degrees were conferred on the 28th ult.:—

Bachelor in Medicine.—Arthur H. Benson, William Blunden, Richard E. Biddulph, George Comyn, John Henry Dwyer, Charles N. Fox, Richard Fullerton, Dudley Loftus Fitzgerald, Charles Gorman, Thomas Kinley Hamilton, James Alexander Greer Hamilton, William Wallace Kemry, Wm. F. Lambert, George Reginald Leeper, Robert M. Maginnis Shapland Newell, David Wilson Orr, Jones Lloyd Peyton, Jonas S. Poole, Edward Richard Power, Oliver Sproule, Sidney Hamilton Taylor, George Whitaker, William Aiken Wright.

Doctor in Medicine.—James Henry Leslie Allen, George Wyndham Crowe, David Drummond, K. M. Franks, William Henry Goode, Nathaniel H. Kane, Alexander Macalister (dip. con.), James Emerson Reynolds (honoris causa), Phineas Barrett Tuthill.

Licentiate in Medicine—Charles Alfred Cooper.

Master in Surgery.—H. E. W. Barrington, Lawrence Corcoran, Charles Featherston, Charles Nugent Fox, Jonas S. Poole.

Licentiate in Surgery.—Martin O'Carroll.

Bachelor in Surgery.—Richard Fullerton, Charles Gorman, Robert M. Maginnis, Jones Lloyd Peyton, Oliver Sproule.

Vital Statistics.—From the Registrar-General's return we learn that during last week 5,754 births and 2,935 deaths were registered in London, and twenty-two other large towns of the United Kingdom. The mortality from all causes was at the average rate of 19 deaths annually in every 1000 persons living The annual death-rate was 18 per 1000 in Edinburgh, 18 i London, 20 in Glasgow, and 24 in Dublin. The annual rates of mortality during the same period in the other large towns were—Norwich 17, Hull 15, Leicester 9, Portsmouth 22, Newcastle-upon-Tyne 19, Birmingham 19, Brighton 19, Leeds 22, Wolverhampton 17, Bradford 21, Sheffield 17, Plymouth 20, Bristol 18, Oldham 28, Manchester 24, Salford 29, Nottingham 13, Sunderland 17, and Liverpool 22. The annual death-rate from the seven principal zymotic diseases averaged 2·8 per 1000 in these towns, and ranged from 0·4 in Newcastle-upon-Tyne, to 7·9 and 8·7 in Portsmouth and Plymouth. In Manchester and Salford 18 more fatal cases of small-pox were registered, including 6 in the Monsall Hospital which had been admitted from the city of Manchester. Since the beginning of the year, 379 deaths in Manchester and Salford have been referred to small-pox, including 93 in the Monsall Hospital. In Liverpool 17 deaths from small-pox were registered last week. In London, there were 3 deaths from small-pox, the mortality from other zymotic diseases being exceptionally low.

Memorial to the late Dr. E. A. Parkes, F.R.S.—The following subscriptions have been received or promised:—The Duke of Westminstnr, K.G., £20; Earl of Derby, £10 10s.; Earl Granville, £10; Lord Belper, £10 10s.; The Right Hon. Gathorne Hardy, M.P., £10; The Right Hon. R. Lowe, M.P., £5 5s.; James Booth, Esq., £20; C. H. Parkes, Esq., £52 10s.; Mrs. William Paget, £25; Sir W. Jenner, Bart., K.C.B., £10 10s; Sir James Paget, Bart., £10 10s.; Sir W. W. Gull, £10 10s.; Sir H. Thompson, £10 10s.; R. Quain, Esq., £10 10s.; J. E. Erichsen, Esq., £10 10s.; Dr. Russell Reynolds, £10 10s.; Dr. Hermann Weber, £10 10s.; Dr. C. J. Hare, £10 10s.; Dr. Bucknill, £10 10s.; Dr. Wilson Fox, £10 10s.; Dr. W. H. O. Sankey, £10 10s.; T. E. Harrison, Esq., £10 10s.; Dr. Philip Frank, £10; Dr. Sharpey, £5 5s.; Dr. Burdon Sanderson, £5 5s.; Henry A. Palmer, Esq., £5 5s.; Dr. Sieveking, £5 5s.; Dr. George Buchanan, £5 5s.; Mr. and Mrs. S. Worsley, £5 5s.; Dr. Carr (Blackheath), £5 5s.; R. B. Smart, Esq. (Manchester), £5 5s.; Dr. Corfield, £5 5s.; Miss Florence Nightingale, £5; Dr. F. Mouat, £5; Miss A. Parkes, £5; Dr. Graily Hewitt, £3 3s.; Christepher Heath, Esq., £3 3s.; Berkeley Hill, Esq., £3 3s.; Mrs. John Rickards, £2 2s.; Dr. Guy, £2 2s.; The Rev. G. C. Bell, £2 2s.; Dr. Charlton Bastian, £2 2s.; Dr. Aitken (Netley), £2 2s.; Professor Rollestone, F.R.S., £2 2s.; Professor Hayter Lewis, F.A.S.; £2 2s.; Dr. W. W. Carr (Blackheath), £2 2s.; J. C. Gooden, Esq., £2 2s.; Dr. F. T. Roberts, £2 2s.; Dr. Gowers, £2 2s.; Professor Fleming Jenkin, £2 2s.; Dr. John Williams, £2 2s.; Marcus Beck, Esq., £2 2s.; Dr. T. D. Griffiths (Swansea), £2 2s.; Dr. Poore, £2 2s.; Dr. De Chaumont, £1 1s.; Dr. Wilks, £1 1s.; Dr. Topham, £1 1s.; Edward Milner, Esq., £1 1s.; The Rev. Jno. Meek Clarke, £1 1s.; Dr. Du Pasquier, £1 1s. Subscriptions may be paid to the Treasurer, Mr. Erichsen, 6 Cavendish Place, W., or to either of the Secretaries. Cheques to be crossed "Union Bank. Post-office orders payable at Vere Street.

On Wednesday last Dr. Risdon Bennett, President of the Royal College of Physicians, presented the prizes to the successful candidates, the principal recipients of which were: For the Entrance Science Scholarships: Mr. H. A. H. Fenton, £60, and Mr. T. D. Savill, £40. First-year's Students: Mr. T. D. Savill, Tite scholarship and certificate of honour; A. Newsholme, College prize (£20) and certificate of honour; J. Shaw, college prize (£15) and certificate of honour. Second-year's Students: C. E. Sheppard, college prize (£15) and certificate; S. J. Taylor, Musgrove scholarship (40 guineas) and certificate; J. Shaw, college prize (£20) and certificate. Third-year's Students: Mr. C. B. Longstaff, college prize (£20) and certificate; C. E. Sheppard, £15 and certificate.

Seaford Convalescent Hospital.—The annual report of this institution has just been issued. The hospital has been established about sixteen years, proving of immense value to the cases which have been sent there. Last year the number of cases treated was 453, of whom 241 were males and 212 females. The number of monthly orders issued since the foundation of the society is to this date 5,550. There had been a falling-off in donations of £506 17s. 5d., and in annual subscriptions of £37 6s.; and as the committee have had to meet the outlay of £4,096 19s. 8d. for increased hospital accommodation and equipment by sale of the residue of the society's investment, viz. £1,738 16s. 4d. of India Five per Cent. Stock, they naturally regret that their funds do not permit them even to contemplate an indoor supply of sea-water on a comprehensive scale.

NOTICES TO CORRESPONDENTS.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Reading Cases.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the **Medical Press and Circular**, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat, after it has passed through the post.

Mr. J. B. B. will find his communication noticed in another column.

Mr. Warner is thanked for his courteous note.

Dr. Wilson.—The local paper to which you refer has not come to hand; we are, therefore, unable to refer to the subject.

Vivisectionist.—1. Originally in the *Spectator*. 2 The same journal referred to the leader in the **Med. Press** on the 1st inst., but did not attempt to refute our arguments.

Dr. Hawtrey Benson has been appointed Medical Referee for Dublin to the Alliance British and Foreign Life Assurance Company, in the place of the late Dr. John Hamilton.

Postal Anomalies.—Dr. Carey, of Taunton, Somersetshire, writes us that by accident there was no postage stamp on the last number of his Journal when it arrived, the authorities in consequence mulcted him of quadruple postage. When the reason of this strange proceeding was demanded, the postal reply was that "the paper was not registered for transmission abroad, and it was therefore charged as a book packet."

[What foreign registration can have to do with any town in Great Britain or Ireland we are at a loss to understand, unless, as our correspondent pertinently puts it, "Taunton being so unlike any other place, it is considered by the authorities as out of the kingdom." However this may be, the said authorities *have received the registration fee* from us for nearly forty years, and on the title page of every number is printed in black type "Registered for Transmission Abroad." Our correspondent does not complain at having to pay the paltry amount, the principle is what he cannot understand, and we regret our inability to enlighten him. We would, however, ask our subscribers who may by accident receive an unpaid copy, to refuse it rather than submit to such a demand. A post card to our office will at any time ensure the transmission of a second copy free of cost.—**Ed.**]

Advertising a Doctor.—A correspondent of the *Melbourne Medical Record*, writing from a town much frequented by Chinese, writes:—"We have a prescribing chemist here who will cure everything while the patient's money lasts, and a doctor who, much to the disgust of the chemist, makes up the medicines he prescribes. Naturally they hate each other, and, as the Chinese element is strong here, both try to monopolise John Chinaman. The doctor, on the strength of knowing a few Chinese words, determined to have a sign-post put up, stating that "Here lives the best doctor in all these colonies: he never kills, but speaks Chinese like a native of Canton." The chemist seeing what was going on, bribed the artist, a Chinaman, with a good dose of opium and money enough to carry him to the new diggings, to write, 'He kills every Chinaman who consults him and then eats him. Go to Dr. ——, the chemist opposite." It was some days before the doctor discovered to his disgust what the Chinamen were laughing at as they passed."

M.R.C.S.—Your communication shall appear in an early number.

A Student.—We must decline your offer.

ON PROTRACTED MERCURIAL SALIVATION.

By Rawdon Macnamara, F.R.C.S.I., M.D. (Hon. Causâ) Univ. Dub.,
Surgeon to the Meath Hospital and to the Westmoreland Lock Hospital, &c.

Cases of protracted, long-continued mercurial ptyalism have become in modern terms of such very rare occurrence that but few living practitioners have ever witnessed [illegible] of them, and it is therefore but little wonder that many eminent authorities should look upon as being apocryphal the reports we read in the writings of the [illegible] surgeons of well-marked, and in many cases startling instances of such events. Thus we find Linnæus, in his "Flora Succica," recording a very remarkable case of a patient who had been subjected to a course of mercury administered after a most imprudent fashion, where the resulting salivation continued more than a year. Swédiaur states that he had witnessed several cases of inveterate mercurial ptyalism which remained for years unamenable to treatment, and which eventually terminated in death resulting on exhaustion.

[illegible], in his "Recherches sur l'Action du Mercure," alluding to these cases, states that he had himself under his care in the surgical wards of the Maison Royale de Santé a wretched man suffering under a most severe mercurial salivation, which, at the time he saw the patient, [illegible] intermission for six years. During [illegible] unfortunate man had derived no [illegible] after a fruitless sojourn in the [illegible] duration, he quitted it in a [illegible] no hope of cure. To give [illegible] of such records the student of [illegible] to recall to mind not only the [illegible] associated with the therapeutic history of mercury, but also the recklessness with which this mineral, as potent for evil as for good, was administered in times gone by, and the then all but universally entertained opinion, insisted upon by Boerhave amongst others, that a salivation to be "a good and efficient one" should produce a flow of saliva to the extent at least of two or three quarts a day.

That a system thus thoroughly saturated with mercury might require a very protracted lapse of time for the elimination of the mineral may, therefore, be well credited, and that during this long period its continued influence might be palpably evidenced over one of the systems of emunctories by which mercury is undoubtedly discharged from the constitution need not excite any great amount of surprise; but that such an occurrence should take place now-a-days—when our practice in the administration of mercury is marked with such extreme caution—is, to say the least of it, worthy of note, and, consequently, I am induced to place on record a case which I recently met with in the discharge of my duties as Surgeon to the Westmoreland Lock Hospital in this city.

Upon visiting my wards on the morning of the 5th April of this year, my attention was attracted by a poor creature from whose mouth saliva was pouring into a vessel placed in a convenient position for its reception. When I say "pouring," I use the term advisedly, for the saliva was flowing out in what may be described as being *pleno rivo*, the amount eliminated in the past twenty-four hours exceeding a quart in quantity. On examination, I found scattered throughout the buccal cavity several small superficial ulcers, and her breath bore the unmistakable mercurial fœtor. Having but that morning come on duty in the hospital, I naturally concluded that her present condition was due to the exhibition of mercury at some very recent antecedent period, but in this surmise I quickly found that I was mistaken, as I was informed that she had laboured under her present symptoms without any intermission, at all events from the 2nd of June in the preceding year—a period of fully ten months' duration—she having been admitted into the hospital on that date, suffering under symptoms precisely similar to those she now exhibited. During this long period every effort had been made, not only by the able and experienced surgeons of the Lock Hospital to arrest the disease, but also by several other medical men in this city, to whom she had from time to time applied, but all in vain. Her sufferings and the remarkable character of her disease so interested me that I made a careful study of her case, and, as a preliminary to the adoption of any plan of treatment, I entered fully into her history, and inquired minutely into the treatment hitherto ineffectually tried. The results as to her history, so far as the hospital statistics go, are embodied in the following tabular statement. I may state that her age when she came under my observation was twenty-seven years:—

	Admitted.	Discharged.	Days in Hospital.	Disease.
1872	Dec. 16	Dec. 21	5	Sore at labium.
1874	Jan. 19	Jan. 22	4	Double iritis.
1874	Feb. 17	March 11	23	Papular rash; iritis.
1874	Aug. 31	Sept. 25	26	Ulceration of throat and of back.
1875	Jan. 12	Jan. 22	11	Patches in mouth and vulva.
1875	March 1	March 19	19	Extensive ulcer on vulva.
1875	June 2	June 22	21	Stomatitis (severe).
1875	June 23	July 8	16	Profuse salivation.
1875	Aug. 2	Aug. 19	18	Ulcerated throat; abscess in axilla.
1875	Oct. 4	Nov. 12	40	Severe ulceration and salivation.
1876	Feb. 7	Feb. 16	10	Ulcerated mouth and throat (patchy).
1876	April 3	May 6	33	Salivation.
1876	June 9	June 20	12	Gonorrhœa; bubos.

A simple perusal of this table must give rise to many melancholy considerations. It is simply deplorable to find that one so young should have led so wretched a life—a life as full of disease as it was of sin. To understand the table fully, a few words of comment are necessary. When first admitted, she appears on our books as being a married woman—aged but twenty-three years—Of the fact of her being married, there can be no doubt, as, by the rules of the institution, to be admitted as such, she must produce her marriage certificate. Between December 1872 and January 1874 we have no record of her having been under treatment, at the Lock Hospital at all events—then comes the history of secondary contamination—and of fresh infection. From March the 1st to March the 19th she was under treatment for an "extensive ulcer on the vulva," the treatment as appears from our books being local and constitutional, the latter consisting principally of tonics, opium, and good diet. She then leaves the hospital, and, as we collect from her own statement, during the period which elapsed between the 19th March and the 2nd of June, she is put on mercurial treatment elsewhere, and returns to us with the first appearance of what subsequently proved so intractable a form of ptyalism. From that date to the 22nd June every effort was made by appropriate treatment to check the salivation, but to no avail, and she leaves the hospital on that date, but only to return next day; her motive in acting thus was to get under the care of the other surgeon to the hospital, in which she succeeded, and remained under his treatment until the 8th of July, when, finding herself no better, she left the hospital to seek relief elsewhere, but to no avail, returning to the hospital in as wretched a state as before on the 2nd August; here she remained until the 19th of the month, her sufferings on this occasion being aggravated by an abscess in the axilla. From this date until the 4th October, she accounted for herself by stating that she in vain sought for relief elsewhere, when we find her returning to hospital, if possible, worse than ever, "severe ulceration and salivation," where she remained until the 12th November, during which long period (40 days) a great variety of treatment was had recourse to, but again all in vain. She then in despair went elsewhere to seek relief, equally ineffectually, returning to hospital on the 7th February, 1876, salivation still persistent, and "ulcerated mouth and throat (patchy);" upon this occasion she remained but ten days, leaving the hospital on the 16th February, to seek for aid in some other institution. On the 3rd of April, hearing that another surgeon had been appointed to the institution, to the vacancy consequent upon the death of Dr. Morgan, she again sought readmission, and thereby came under my care. Here I may be permitted to pause to place on record my humble tribute to this gentleman's memory—to state how earnestly I mourned in him the loss of a colleague endeared to me by many genial associations, by pleasant memories, but, beyond all, by high professional bearing, united with an earnest desire to advance surgical science by strict adherence to everything that should characterise its votary—zeal, learning, intelligence, humanity, truth. Well as I thought that I knew him, it remained for me, when compiling the facts for this short paper, to learn what our art has lost by his premature death.

After this brief *résumé* of the history of this poor creature's medical life, it remains for me but to give a short summary of the various treatments to which previous to coming under my care she had been subjected with a view of giving her some relief to her sufferings. To enumerate all the various medicaments employed would be but to emulate in prolixity the catalogue of ships in dear old Homer. Locally and constitutionally every approved plan of treatment seemed to have been exhausted, hygiene had been equally appealed to, and yet all had proved ineffectual. Doctors had been changed, hospitals also, and yet the salivation continued, and it seemed as if her case was to rival that already alluded to as occurring in the practice of M. Colson. Upon a careful review of all that had been tried, I found that but one remedy remained unappealed to, and that was acetate of lead. Years since, while still serving my time to the late Sir Philip Crampton, I overheard my highly esteemed friend and colleague Mr. Wharton alluding, in a conversation he had with the late Mr. Smyly, to the value of this salt when administered internally in the treatment of severe salivation. I believe that to Mr. Daniell the suggestion is originally due. From that time, now many years since, I never had met with a case such as this, giving me an opportunity of practically testing the value of this plan of treatment. I determined to place this poor woman on a steady course of acetate of lead, combined with the pharmacopœial solution of acetate of morphia. The treatment was continued for twenty-seven days, and at last I had the satisfaction of seeing her leaving the hospital on the 6th May, completely not only relieved, but cured of her long continued, troublesome, and disgusting complaint; that the sugar of lead was the principal factor in her cure, that the morphia had but little, if anything, to say to it, was demonstrated to my mind by the fact that opium and morphia had been previously ineffectually employed on several occasions in the treatment of her case. In addition to the constitutional treatment, local means were also employed; that these assisted in effecting the cure may be admitted, but that they were the important elements cannot be granted, for the local means had recourse to were only such as had previously been repeatedly tried without curative result; and I can ascribe the cure to no other agent than the acetate of lead. That the cure was permanent, was proved on her re-admission on the 9th June, suffering from gonorrhœa, but not from any sign or symptom of salivation.

I think that it must be admitted that in all such cases of protracted salivation, the occurrence must be attributed to some idiosyncrasy existing in the patient, which determines the developement of this most untoward symptom. Large and long continued mercurial courses in days gone by were the rule, yet this result was the exception; so we cannot ascribe it to this cause. Again, unusual susceptibility of the salivating properties of mercury may exist in the individual, and yet we do not in such cases find that the sialogogue effects continue any undue length of time. Many most remarkable instances of exceptional susceptibility of the sialogogue powers of mercury have been placed on record, but none more remarkable than the following, for the truth of which I can personally vouch. A young gentleman contracted syphilis, for the treatment of which he was placed upon mercury. There was nothing noteworthy in the case, so far as he was concerned. In due course he was salivated, having during the entire period of his mercurial treatment been confined to his bed-room. After several days his brother called to see him, and sat in the room with him for a couple of hours, and on leaving, perceived an unmistakeable mercurial taste in his mouth; next day he was salivated, and the ptyalism lasted for several days, not severely, but unmistakably. Both these gentlemen are still alive. In this instance we have most unusual susceptibility, but by no means unusual continuance, of the sialogogue effect of mercury, so that I feel myself justified in not looking upon these two conditions in the light of cause and effect. M. Colson mentions some cases analogous to, but not as remarkable, as this one in his "Recherches sur l'Action du Mercure."

That several other medicines as well as mercury may produce salivation is well known, but I believe that in such cases the ptyalism is never of the persistent character here recorded. That salivation may arise from local causes (carious teeth, foreign bodies in the ear, &c.), and that it is occasionally a symptom in pregnancy, is also well known, but I believe that in all such cases the maxim holds good, "Sublatâ causâ, tollitur effectus." But that salivation may occasionally occur as an idiopathic affection, and prove equally obstinate as when of mercurial origin is probably not so generally known. Such, however, is the fact, and scattered throughout our literature cases of the kind are to be met with. Graves, amongst other writers, having recorded in his Lectures on the Practice of Medicine a remarkable example of this disease. (Second Edition, vol. ii., p. 478, *et seq.*)

To allude, in its social bearing, to the table in which I have recorded the number of times this wretched woman was in the hospital, would be quite foreign to my object in penning these lines; yet I may be permitted incidentally to observe that an inspection of this table, which may well be termed the calendar of a prostitute, must give rise to grave consideration in the minds of every thoughtful man.

◆

THE PHYSIOLOGICAL FUNCTION AND ANATOMY OF THE CRYSTALLINE LENS

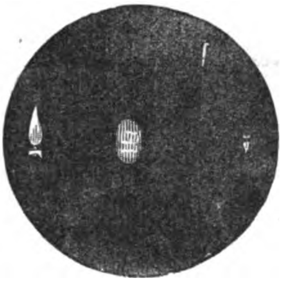
A LECTURE DELIVERED TO STUDENTS.

By Archibald Hamilton Jacob, M.D. Dublin, F.R.C.S.,
Surgeon to the Dublin Eye and Ear Infirmary; formerly Ophthalmic and Aural Surgeon of the City of Dublin Hospital.

(Continued from page 44).

Without following further the many hypotheses which were put forth to account for accommodation, it is sufficient for me to say that it has been conclusively proved that the lens is the essential agent, and I will proceed to explain to you how this has been shown to be the fact, what the changes are which it undergoes, and by what agency they are produced. As far back as the year 1801 Thomas Young published, in the "Philosophical Transactions," a paper in which he attributed the accommodative power of the eye to a change of curvature, and, therefore, of refractive power of the lens, which, however, he wrongly attributed to a contractile power in the lens fibres. Until 1849 Young's experiments remained unproductive and his theory neglected, at which time Langenbeck brought to bear a practical proof of the truth of Young's theory and a conclusive evidence that the lens does actually change its curvature for the purpose of accommodation. Probably the theory of Young received less attention than it deserved, because he himself and all physiologists of his day were ignorant of the existence of muscular elements in action within the eye, and he was obliged to support his theory by a hypotheses that the lens fibres were contractile in their nature. It was to Langenbeck that first occurred the method of actually demonstrating the changes in the lens in accommodation, though it remained for Cramer and Helmholts to attach to the observations their due significance. It had been discovered by Purkinje as early as 1823, that if a light were thrown obliquely upon the point of the eye and its reflection received by the eye of an observer, it would produce three reflected images, although these images can be accurately observed only by an instrument specially made for the purpose. Any person can observe them for himself by seating a patient at a table and directing him to look straight forward. Then placing a strong light on a perfect level with the pupil and at an angle of 30 degrees from the axis of the patient's eye and seating himself at the side of the patient opposite to the light, and with his eye at exactly the same level as the lamp and at exactly the same angular distance from the axis of the patient's vision, the observer will recognise apparently in the pupil three reflected images as depicted in Figure 1.

Fig. 1.



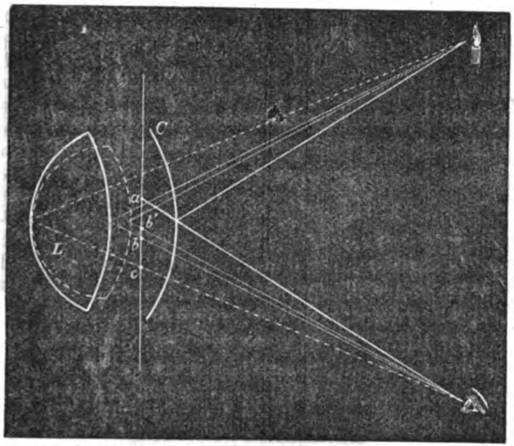
Let me explain how these images are formed and what they show. We know that a convex mirror will produce a diminished erect image *behind* it and a concave mirror a similar diminished image *in front* and inverted. Without entering into the optical causes of these reflections, it is sufficient to say that they may be well seen by observing the images of a candle thrown from an ordinary double convex spectacle glass in a dark room. It will be seen that the front or convex surface of the spectacle glass produces a diminished erect image behind, and that the back of the lens produces from its front or concave surface an inverted image in front of the lens. These reflections from the curved surface within the eye are as depicted above. The flame thrown upon the surface of the cornea in the position I have above described is reflected by three mirrors, the anterior convex surface of the cornea, the anterior convex surface of the lens, and the posterior concave surface of the lens. It produces thus an erect bright image from the corneal surface, a second erect image from the anterior convex surface of the lens, this image being, however, very dull, because the mirror surface of the lens is, so to speak, backed with pellucid material, and a third inverted image from the anterior concavity of the back curvature of the lens.

The thick line of the pencil proceeding from the flame represents the ray reflected from the convex corneal mirror b it produces an erect image behind the cornea which appears to the observer's eye to be situated at A, and is represented in Figure 1 by the small flame. The intermediate thin lines represent the path of the rays reflected from the front corneal mirror during accommodation for distance and for near objects. These rays also produce erect but dull images which appear to be situated at b′ and b′ according to the position of the reflecting lenticular surface.

The external dotted lines represent the path of the ray which strikes the concavity of the back of the lens, and it produces an inverted diminished image in front of the reflecting surface, appearing to the observer to come from the point c. The patient being in position is directed to look straight forward at a distant object, and the appearance seen by the observer is, as we have said, represented in Figure 1.

The accompanying diagram will explain the position of these images.

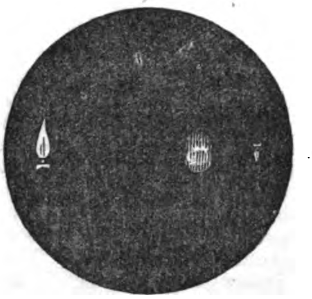
FIG. 2.



The left-hand large flame is the corneal reflexion, the spot in the centre the anterior reflexion of the lens; the small inverted flame at the right hand is the posterior lenticular image. The patient is then directed to concentrate his vision on a near object, and immediately the blurred intermediate image is seen to move towards the inverted image. And the images assumes the position represented in Figure 3.

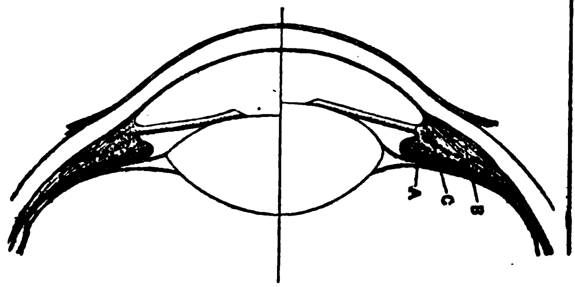
In other words the image c, appears to move to c, because the reflecting surfaces, *i. e.*, the front of cornea and front of lens come closer together. It was therefore concluded that the lens become thicker, as shown by the dotted lines in the diagram Figure 2, when the eye was accommodated to near objects.

FIG. 3.



The change which is believed to occur is properly represented in the accompanying sectional diagram, in which the left-hand half A shows the condition of the lens iris and ciliary muscle when the eye is in a state of rest, *i.e.*, accommodated for distances, and that on the right (B) when accommodated for near objects. It will be observed that the lens is conceived to undergo in the act of near accommodation an alteration of shape, increasing in thickness, and presumably shrinking in diameter, and that the iris at the same moment contracts, thus confining the rays to a still smaller area of the lens surface. That such a change appears visible to observation I have already shown and Cramer and Helmholtz have, assisted by Bowman's examination of the ciliary muscle, and by Græfe's clinical observations, produced an explanation of the act of accommodation which coincides closely with the phenomena which are observed in certain pathological conditions of the eye.

A FIG. 4. B



To appreciate this explanation, a reference to the anatomical structure of the parts which are presumed to react upon the lens is necessary.

The lens fibres are enclosed in a strong cartilaginous bag called the capsule, the special attribute of which is its elasticity, which is quite obvious to a superficial observer. This capsule and its contents occupy, when detached from the influence of its connexion, the thicker form which it takes on near accommodation and which is represented above at B, and the entire lens, if subjected to a gentle antero-posterior squeeze, will yield and become thinner, and when released will resume the thicker form and higher refractive power.

It is thus evident, that if the lens were—when at rest within the eye—free to adopt its own shape, the eye would be always accommodated for near objects and would be useless for the ordinary purposes of life, and it is necessarily presumed that the periphery of the lens is continually under tension, which flattens its form and maintains it in that condition. This tension cannot be muscular in its origin, because to conceive it so, we should suppose the muscular spasm to be constant and unremitting—a condition which cannot exist—and because it has been conclusively demonstrated that muscular relaxation is accompanied not by a shortening of sight (*i.e.*, by a thickening of the lens), but by the contrary condition, and we therefore seek for the cause of this tension in the passive elasticity of the structure attached to its circumference, and we assume that the muscular effort of near accommodation takes effect by counteracting this elasticity, and thus relieving the lens capsule of the force which prevents its assuming its natural curvature. The lens is maintained in its position by the suspensory ligament known as the Zonule of Zinn. This attachment seems to be simply a thickened expansion of the hyaloid membrane, which encloses the vitreous humour, and it takes its origin from the margin of that body, just where the retina terminates, close to the posterior limit of the ciliary muscle. It is highly elastic, and its elasticity and strength are increased by the interweaving of radiating fibres of elastic tissue. It lies between the ciliary processes and the lens, and is attached to the anterior capsule, leaving between itself and the vitreous a space about the twelfth of an inch wide, immediately abutting on the edge of the lens known as the canal of Petit, within which the edge of the lens is supposed to advance and recede during the changes of its form which take place in accommodation. To account for the continuous flattening of the lens, this suspensory ligament is presumed to keep up an elastic pull upon the capsule. Outside, or rather in front of it, are placed two structures, which are depicted in the foregoing illustration A the ciliary processes, and B—C, the ciliary muscle. The former of these is not proved to have much to say to the accommodation function, although it has been stated by Ch. Rouget that the annular fibres of the ciliary muscle by contracting compress the irido-choroid venous trunks, and thus forcing all the blood to pass through the ciliary processes, give rise to erection or rigidity of these organs, and he asserts that while thus erect the organs become fitted to transmit to the crystalline lens, in a modified form, the pressure exercised by the ciliary muscle. The ciliary muscle (B—C in diagram), now universally admitted to be the active agent in accommodation, was long ago known as the ciliary ligament, having received that name in consequence of the white ligamentous appearance which it presents when the sclerotic is stripped off it and off the choroid. It was first proved to be muscular in its nature by Bowman, and it was divided by Von Reeken and Müller into two parts, into a longitudinal (B) and a circular (A) muscle. This organ takes its origin from the angle between the membrane of aqueous humour, or membrane of Descanet, and the iris; the longitudinal from the former, and the circular from the latter structure. The longitudinal fibres (B) pass backwards just within the sclerotic, and are attached into the connective tissue of the choroid just where the retina ends, and where the Zonule of Zinn takes its origin. The circular fibres (A) are wider in their meshes, and spread out upon the ciliary processes, being, as I have said, supposed to constrict the venous trunks, and thus erect the corpus ciliare.

The actual mechanism of accommodation, so far as it is yet best known, may thus be recapitulated as follows:—

a. The baccillar or Jacob's layer of the retina becomes conscious of the confusion of the image produced by a near object upon the retina, and reacts (as is supposed through the ciliary ganglion) upon the brain, the stimulus being reflected through the ciliary nerves to the ciliary muscle.

b. The ciliary muscle contracts. By its circular fibres it is presumed to constrict the venous trunks, thus preventing the return of the blood from the iris and corpus ciliare to the vasa vorticosa of the choroid, and producing erection of the ciliary body. By its longitudinal fibres it draws together the anterior limit of the choroid, and the posterior margin of the back layer of the cornea.

c. The posterior attachment of the suspensory ligament of the lens being thus drawn forwards, the elastic tension of that ligament is counteracted, and the lens is left free to assume its natural shape.

d. Thus relieved of control, the elasticity of the capsule causes the lens to become thicker. The back of the lens being firmly attached to the vitreons scarcely alters at all. The apex of the front advances towards the cornea pushing the iris before it, and the periphery of the lens recedes slightly within the canal of Petit.

(*To be continued.*)

◆

THE CONSERVATIVE TREATMENT OF PARONYCHIA OSTEOSA.

By Frank Thorpe Porter, L.R.C.S.I.,
Demonstrator, Ledwich School.

Of the many surgical diseases to which the human frame is prone, none claim more attention at the hands of the surgeon than paronychia osteosa, whether it be viewed in relation to the present suffering induced by it or to the subsequent disfigurement which too often follows in its track.

It is a subject which, viewed from a conservative aspect, has not received the notice at the hands of surgeons to which it is entitled. My object in approaching the subject is to endeavour to place on record the advantage of resection as opposed to the more usual treatment by amputation in such cases.

I shall briefly state the particulars of four well-marked cases with a view to illustrate the mode of treatment followed up by me.

Case No. 1.—The patient, an old woman, came under my observation as far back as January 1874, at which time she had been suffering from the disease for a period of three weeks. The entire of the ungual and the distal end of the proximal phalanx of the left thumb were in an advanced stage of necrosis. I removed the diseased portion of bone by twisting with an incisor tooth forceps, preserving the soft parts, including the nail; the parts were dressed with lotio nigra, and healed in ten days. The patient has much power of movement of the thumb, it differing from that of right side by its diminished length only.

Case No. 2.—A middle-aged woman came under my notice in March, 1874. The details of the case were precisely similiar to No. 1, with the exception of the circumstance that the bones were subsequently regenerated.

Case No. 3.—A woman aged 40 came under my notice on the 9th of January last. In this case the right index finger was the part implicated, and must have been the seat of severe inflammation for several days previous to the patient consulting me. I made free incision along the palmar aspect of both ungual and middle phalanx, finding however that very little pus was present; the tendons were softened, and the entire ungual phalanx and distal end of the middle extensively necrosed. On questioning the patient I ascertained that she suffered from *dull nocturnal* pain for several weeks before any swelling set in in the finger, a circumstance which is a sure diagnostic sign of the existence of the osseous form of paronychia. The diseased portions of bone were removed as soon as I ascertained them to be loose. The parts took three weeks to heal, and would have healed sooner, perhaps, were it not for the weak constitution of the patient, who has now considerable power over the finger, although it cannot as yet be completely extended.

Case No. 4.—The patient, a middle aged-man, by occupation a butler, came under my charge in the middle of last April. The right index was also affected in this case, and nocturnal pain was present for *three weeks* before the appearance of any swelling. Free incision disclosed destruction of the entire middle phalanx and base of the ungual. An hospital surgeon who saw the case advised immediate amputation of the entire finger, to which operation the patient refused to submit. I subsequently removed the whole of the diseased bone by an incision from behind with the aid of a forceps and elevator. The distal extremity of the ungual phalanx together with the soft parts including the nail were left. The soft parts healed, however, very slowly, in consequence of the time required to fill up by granulation the great space (the patient has very large hands) occupied by the middle phalanx, which was considerably over the average size. The patient can now use the finger remarkably well, and can hold a moderate weight, wield a stick, sweep with a brush, &c. There is no disfigurement save a slight depression. The causes assigned by the patients in the above four cases were—in No. 1, a prod of a fish-bone; No. 2, do., of a needle; No. 3, matter from a boil which the patient was dressing for a friend getting into a "chap" or "abrasion" on the finger; No. 4, the irritation of some plate-powder which the man was using when suffering from "chaps" on the hand. With reference to the precise *nature* of the disease, I am not in a position to hazard an opinion further than to remark that the fact of its being essentially a non-contagious and non-infectious disease clearly proves that it is not an erysipelatous affection as is frequently assumed. No surgeon would have the least dread of erysipelas following an operation because there was a patient suffering from paronychia in a neighbouring bed. I also consider it a mistake to suppose that true paronychia osteosa begins in the soft parts. From long observation I have arrived at the conclusion that the bone is necrosed long before there is any inflammation in the soft parts. Necrosis as a rule is antecedent to changes in soft parts; there is no reason why the phalanges should follow a different rule from other bones; the changes in the tendons and other soft parts are the result of an effort of nature to get rid of a bone that is primarily diseased.

The treatment which I follow has the following advantages, viz.—1. A moderately useful finger is preserved; 2. The symmetry and appearance of the hand is not as much altered as in amputation. 3. By retaining the pacinian corpuscles the tactile function is intact, a matter of importance in the following of many pursuits in life. The great disadvantage is the length of time the parts take to granulate.

Each mode of treatment has its advocates, there being such a differenee of opinion, even between authorities of the greatest eminence, that one knows not what course to steer in the face of the confusing fog of contending genius. Writing on the subject of paronychia, Mr. Syme states: "When the tendons or bones are destroyed, *amputation must be performed*, (a) as the finger, even though it might be healed, could not be of any service to the patient" (*vide* Syme's "Principles of Surgery," page 431, London, 1856). Hear another opinion on the same subject from the pen of Gross: "Dead bone is removed as soon as it is easily separable, the periosteum being as little interfered with as possible, and *amputation always avoided*, (a) experience having shown that a new phalanx is sometimes formed, and even when this does not happen the boneless finger will be both useful and sufficiently seemly" (Gross's "System of Surgery," vol. ii., page 1134, Philadelphia, 1859). My own experience favours the latter opinion.

In conclusion, I will say that it will afford me pleasure to contribute the notes of any fresh cases which may come under my observation.

◆

ANIMAL VACCINATION.

THE VACCINAL STATE INSTITUTE OF BRUSSELS, CREATED BY ROYAL DECREE OF JULY 11, 1868.

Under the direction of Docteur **Warlomont**, Membre Titulaire of the Royal Academy of Medicine of Brussels.

(Translated at his request by Dr. C. R. **Drysdale**, of London.)

(Continued from page 48.)

In Belgium, during the epidemic of 1870-71, which raged especially on account of a rigorous winter, the institutes of human vaccine did everything in their power to procure vaccinifers; but we should have an idea of the insufficiency in which the service of re-vaccinations would have found itself, if we had not possessed the Vaccinal Institute of the State, when it is known that this establishment has distributed, during more than six months, animal vaccination for more than 500 vaccinations *daily!* Thanks to the existence of the institute, vaccine lymph never was wanting one instant, in spite of the prodigious quantity of demands to which it has to reply. Ninety-nine times in a hundred the emissions were made, as they still are, by return of post, so that, put in the post before the last evening collection, they arrived at their destination in every corner of the country, transmitted by night trains, in the morning of next day. The service has never been interrupted for an hour, nor has the practitioner had more than twenty-four hours to wait. With the same eagerness and the same punctuality we have satisfied numerous demands made from abroad.

The Vaccinal State Institute is installed in the Zoological Garden of Brussels, where the society has built a *locale* for this purpose, which it leases to the Government. It is composed of a waiting-room for the richer class which may come to be vaccinated there, of a great waiting-hall for the poorer classes, of a study, and of another room provided with the necessary furniture. It is in this room, which is in communication with a little stable large enough to hold six calves, that the animals are brought, to be placed on tables which can be moved, where they are solidly fixed during the whole time necessary for the operations which require at one time the insertion on some of them of the lymph, and at another time the collection of the product obtained, at another of the vaccinations. (a) This little stable communicates with the farm of the Zoological Garden, and it is by this communication that the animals are introduced, nourished, cared for, and their cowhouse kept in the state of cleanliness required. The calves are brought regularly as they are required by a butcher, who hires them to the establishment for seven days; after this time, they are restored to their proprietors, after having served for vaccination and the harvest of lymph, and without having undergone, from these, any sensible depreciation: they are fed on eggs and milk. In ordinary times two calves a week are enough; during the epidemic of 1870-71 one at least was vaccinated every day.

The day when the animal is to be vaccinated, or rather the evening before, for we must not leave the hair time to grow again, it is fixed on the movable table and shaved, a laborious operation which is abandoned to a labouring man: the surface to be shaved ought to be about equivalent to that of the crown of a hat, and should extend from the inguino-mammary region in the direction of the umbilicus. It is on the surface that the insertions should be made, by the deposits of liquid vaccine, borrowed in the same place from the vaccinifer calf which is fixed on a second movable table, into incisions which scarcely cut more than the epidermis, and of the length of about a centimetre.

These incisions ought to be made in the direction of the axis of the animal, in order that, further on, when the pustules are utilised, the clamps fixed upon them may not be removed by the movements which annoyance or pain causes the animal to make, and which elongate the longitudinal axis at the expense of the bilateral axis. The incisions are about two centimetres distant from each other. The animal being extended on one side, when the operation is finished, they seem like a series of ladders situated side by side and distant two centimetres from each other, the distance which is that also separating the steps from each other. In order to leave entire liberty to the growth of the vesicles, it is well that the steps of the two neighbouring series should be contrary to each other. In some forty-eight hours, if the inoculation is to succeed, each incision is already surrounded by a slight red border, which, in twenty-four hours further on, rests on an induration the volume of which rapidly augments, and ends, at the end of the fourth or fifth day, according to climate and season, in vaccinal vesicles.

These vesicles have the form of a coffee-bean, with longitudinal cicatricial depression, surrounded by a zone, silver-white and transparent, itself encased in another red zone. The little tumour developes itself still further during the seventh and eighth day; the transparent zone takes on a white, chalk-like, and then yellowish colour; on the following days, the pustule becomes purulent, and then dries up, and is transformed into a blackish crust, which hardly falls before the fifteenth or twentieth day.

The contents of the vaccinal tumours thus obtained is scarcely serviceable except during twenty-four hours; in order to avail ourselves of it with advantage for vaccination and for collection of lymph, we must choose the opportune moment. Now this moment, which experience alone teaches to recognise well, and which is that wherein the whitish areola has its transparent appearance and silvery colour, varies according to the temperature: in summer it generally occurs in the course of the fifth day, in winter in that of the sixth. There may thus be twenty-four hours of margin, during which the matter is preserved; we must not count upon this: the most favourable moment is that most near the one where the silvery areola has commenced to appear, under the form of a small white border parallel to the incision, or rather to the scar which replaces it.

(a) Italics are mine.

(a) The Vaccinal State Institute is only destined, by virtue of its statutes, to the culture and harvesting of animal lymph. It is by exension and from pure philanthropy that the direction also makes it serve for vaccination, which is gratuitous for the poor.

In the vesicles of human vaccine, the fluid matter is distributed in such a way in the parenchyma of the little tumour, that it transudes from it in the form of transparent drops as soon as it is slightly punctured by a lancet or a needle through the external envelope. In those of animal vaccine, this is not so, and we may transpierce even extensively the external cuticle without seeing the smallest drop of pus come forth. We must here, then, as well for vaccinating as for collecting the lymph, make the latter issue forth by compression of the tumour. We have constructed for this purpose a curved forceps, exercising a pressure which is kept up by means of a ring. This forceps must be placed so that its convex extremity may constrict the base of the tumour and not the tissues seated beyond, in case of calling forth inert liquids; the upper part of the forceps limit the tumour itself on each side, and equally prevent the liquids to escape by the sides. It is then the escape of vaccine lymph alone which is promoted. At the moment when the forceps are pressed together by the ring, we usually rub, gently but quickly, the surface of the pustule with the handkerchief, which rapidly removes the cicatricial crust and drop of blood which at first presents itself. This done, the parenchyma of the tumour is made free and gives up its contents, limpid and free from all foreign particles, either to the lancet or to the ivory point which is to remove the desired matter.

For vaccination we make use of a grooved needle, or any other appropriate instrument. A simple insertion beneath the epidermis suffices when we act with living vaccine. When preserved vaccine is used, whether human or animal, we must open for the entrance of the lymph a larger orifice, open to the air, as we shall describe further on.

For the collection, we employ two methods—the preservation in a liquid state in tubes, that of a dry state on ivory points.

A. In order to collect the animal lymph in tubes, we must take it as follows: we place in a porcelain capsule the contents of a certain number of vesicles expressed by means of the forceps constructed for this purpose, and which has been collected with some sort of curette. In the liquid thus collected, a few drops of distilled water, with glycerine in it, are thrown; this is mixed, and the detritus is separated, the residuum or coagulum, which is carefully compressed, and which contains blood globules, fragments of epithelium, &c., and we pass into the tubes the liquid, which, thus cleansed and freed from its coagulating principles, enters and is well preserved without being exposed to coagulate again, as takes place when introduced into the tubes without undergoing this preparation, as has with truth been urged against it.

The tubes we now make use of are cylindrical, without any median swelling, and tapering at their ends, in order to be more easily occluded; it suffices, indeed, to put them to the flame of a candle to see them immediately get red and thus give the guarantee of being exactly closed. The other means of occlusion, sealing-wax, &c., are far from beng equally faithful.

Animal vaccine thus prepared is preserved relatively pretty well, but much less time, however, than human vaccine collected directly in tubes. We can hardly count on them longer than a week; and it is the more certain as it is employed to the moment which is the nearest to that in which it was obtained.

It is because of this inconstancy of the activity of fluid vaccine that we much prefer the following method:—

B. *Vaccine* (*Animal*) *on Points.*—The points we employ are ivory plates, square at one end, pointed at the other, five centimetres long, seven millimetres wide, of the thickness of an English playing card. When the compressing forceps are applied, we plunge the point in the matter which presents itself at the surface of the pustule, so that it becomes covered with lymph on its two faces, and for an extent of one or two centimetres, commencing from its point. It is then placed on the bottom of a plate turned upside down, the base resting on the circular ledge which it has, and the point directed towards the centre of the plate: thus inclined, it is towards the point that the liquid flows which has just been received; thirty or forty are thus disposed in a radiating manner, one beside the other, on the bottom of the plate, and these are exposed either to a hot sun or to the radiation from a fire giving a heat of the same intensity. In a quarter of an hour, the deposited lymph is dry by evaporation of its liquid part, and the point is fit for use. We have, however, the custom to dip it again, either the same day or on the morrow, a second time, and thus clothe it with a second coat like the first, and even with a third, if the materials and the time admit of it. We even take care, in order to avoid lest the lymph of the first coating be lost from the porosity of the ivory, to plunge it for a shorter or longer time beforehand in a solution of gum arabic, which thus coats it with a preservative varnish, which is allowed to dry well.

Thus prepared, our vaccine points preserve all their power for weeks, months, and even years, which is explained by this—that the liquid part having removed by the evaporation from the solid parts or granulations of vaccine those elements which promote putrefaction.

In order to make use of the points, we must open a gate of entry for the lymph larger than punctures make, and for this purpose we must act as follows:—

Deposit on one of the faces of the ivory plate, and then on the other, one drop of *tepid* water, which is left there until the lymph is well softened. Then make, at one millimetre from each other, two or three scarifications of about four millimetres long, only cutting through the epidermis, or, better still, one circular incision by means of the *vaccinating trephine*. If a little blood flow, let it dry; then draw over the wound, when quite staunched, for some time, and on its flat side, the plate charged with well-softened animal vaccine. If any blood has been mixed with it, collect all on the incisions and let it dry there.

Vaccination by scarification still meets with a few opponents. They reproach it with being painful and difficult, with giving place to hæmorrhages and over-large vesicles, as well as of frightening the infants and their friends.

The employment of the *vaccinating trephine* meets all these accusations. It is composed of a circular plate of two millemetres in diameter, enclosed in a case of cylindrical form. A movement of rotation is administered to this by the play of an interior spiral. Closely applied to the skin made tense, it suffices to press rapidly with the end of the index on the button to put the plate into action, which traces with the quickness of lightning a round furrow of depth proportionate to the projection given to the plate—a projection which is increased or diminished by turning up or down the protecting screw. The incision once made, the lymph is applied as usual. (*a*)

Persons have said that animal vaccine ought to have less power than human lymph, since it has required a new process to introduce it. This is an error. The vaccination by scarification is no new process; it has for many years been made use of in England and in Belgium. On the other hand, it has not been invented solely in view of the use of animal vaccine; all vaccinations with *preserved* lymph ought to be made largely and open to the air, if we wish to assure its success.

We have completely abandoned the mode of preserving vaccine between plates of glass, which the blindest routine can alone still keep up: if we wish by this means to have liquid vaccine, we only can do so by taking precautions which demand much time and care: we must preserve the matter from contact with the air, if we expect to succeed, by surrounding with the greatest care the edges of the plates with lead or tin foil, which is perfectly illusory, or

---

(*a*) The instrument is made by M. Denis, rue du Marché aux Herbes, 79, à Brussels, price 20 francs.

preserve its freshness by surrounding with leaves of freshly-cut plants, or placing them in cool and damp places, &c. And when we have done all this, we have obtained nothing comparable with the lymph of tubes. Do we desire to have dry vaccine in store? Well, then, the difficulty is still greater: the liquid parts having been only very slowly removed, have permitted a putrid alteration to ensue, and the *quelque chose de sec* which is then found between the plates so carefully filled is absolutely inert. What a number of misfortunes we thus arrange for ourselves, what loss of time, what difficulties in sending to a distance. In place of this, our tubes placed in wooden cases, our points affixed to a paper of instructions which accompanies each emission, the one and the other introduced into a common envelope, and dropped into the post, arrive without injury, without difficulty—with the rapidity and facility of an ordinary letter—to the most distant destination.

These data justify the considerations which we have made to prevail when we proposed, in 1868, to the Minister of the Interior of Belgium, the creation of a central establishment of vaccine founded upon animal vaccination. And in paying attention to us, the Government of Belgium has been the first and only one, we think, until now, to offer to public hygiene this precious resource, the value of which is more and more being appreciated every day.

Clinical Records.

METROPOLITAN FREE HOSPITAL.

Cases seen by Dr. CHARLES DRYSDALE.

CASE I.—*Syphilitic Epilepsy.*

A YOUNG woman, Mary P., aged 23, came to the Metropolitan Free Hospital, on July 4th, complaining of severe fits, which had supervened some six months before. Patient had had six fits, during each of which she fell down, was convulsed, (as she was informed), during a longer or shorter period of unconsciousness, bit her tongue, and frothed at the mouth. Her first fit appeared after the birth of her second child. The first child was still-born. The second was born at full time, but it was soon covered with eruptions, snuffled, and died in some two or three weeks greatly emaciated. About three weeks after her last confinement patient had her first fit, which was a rather severe one. No fit had ever been experienced by her in her previous history, either in childhood or at or after puberty. On interrogation, it appeared that when in the fit her left arm and left leg alone were violently convulsed, and her mouth was seen to be violently drawn to one side.

Remarks.—Syphilitic epilepsy is constantly misunderstood. There can be no doubt that when an adult, male or female, suddenly becomes affected with epileptic seizures in the midst of health, syphilis is in most cases the hidden cause of the seizure. In this case the history of syphilitic children was, of course, a great guide, but the mother had had herself but scanty symptoms of the disease which had destroyed her offspring, with the exception of a few cervical enlarged glands; there were but few marks of any poison having entered her system. The treatment recommended was ten-grain doses of iodide of potassium thrice daily.

CASE II.—*Smoker's Tongue.*

A man, aged 66, Daniel Sibourn, a seafaring man, came to the Metropolitan Free Hospital on June 30th, 1876. More than seven years before being seen he had noticed a *blister* on his tongue, which he had at that time put down to his smoking coarse tobacco. He has been a *very great* smoker of tobacco. For thirty years past he had used at least an ounce of shag tobacco daily. Having lived a rough seafaring life, he had kept good health all the time. He had smoked a little since the age of fifteen, but latterly much more. Patient observed that he had often fits of great dyspepsia and dimness of sight after smoking a little more than usual. *The tongue* was seen to be small, reddish, and fissured at the tip; covered over the whole of the dorsum with an opalescent pellicle. A similar patch of opalescent appearance was seen to exist on each side of his mouth, at the commissures of the lips, extending over the inside of the lips for some half-an-inch.

CASE III.—*Salicylic Acid in Acute Rheumatism.*

A young man, Charles Dedman, aged 25, barman, was admitted into the wards under Dr. Drysdale's care on May 19th, 1876. Taken ill a week with headache, pain in limbs—vomited on admission. No previous attack. Father reported to be rheumatic. Temperature, 7 p.m., 102·4. On May 20th, at 10.30 a.m., patient had a temperature of 103·1, pulse 104, and respiration 30; tongue furred, rather dry. There was pain with swelling of ankles and knees, pain in hips, and a little in the left elbow; a little in shoulders and left wrist. He was put on low diet, with two pints of milk, and had forty grains of bicarbonate of potash every second hour. On the same day, at 8 p.m., he perspired freely, and his temperature, was 103·6, with a pulse of 128.

On May 21 he had passed a restless night, dozing at intervals after taking ten grains of Dover's powders. Perspires freely. Has pain in ankles and knees, also in right arm and fingers of right hand; pain in loins also. At 1 p.m. on that day his temperature was 103·2; it fell to 102·6 at night.

The treatment with bicarbonate of potash was continued until June 9, and the morning temperatures were as follows: May 22, 102·6; May 23, 102·3; May 24, 102·4; May 25, 102; May 26, 104·4; May 27, 103·6; May 28, 103·4 (on this day a systolic murmur at apex was first heard); May 29, 102·2; May 30, 101; June 1, 100; June 2, 100; June 3, 100; June 4, 101·6; June 5, 101·6; June 7, 101; June 8, 100; June 9, 100·6; June 10, 100·5; June 11, 100 (sharp pain at lower part of sternum); June 12, 101·5; June 13, 102·2.

On June 14th the morning temperature was 101·1, and the evening was 102·4. He perspired very freely. *Salicylic acid was now* administered first in one dose of 20 grains, then in four doses of ten grains, then 20 grains about 9.15 p.m. At 6 p.m. the temperature was 101·9.

On June 15th the morning temperature fell to 99·2, and the evening to 99. In the afternoon *salicin* was given in ten-grain doses, the last about 9.40 p.m. The temperature rose to 100·6 June 16th, temperature 99·5. During the day he had ten grains of salicin every two hours; but on the 17th the morning temperature rose to 100·1, and the evening to 101·1 Accordingly *salicylic acid* was given again in the evening in a twenty-grain dose at 7.10. He sweated greatly after this; at 8.35 he had another dose, and at 10.20 he was drenched in perspiration, with a temperature of 99·8. On the 18th he felt better; there was less pain, but his appetite was bad. About 5 p.m. he had twenty grains of salicylic acid, and this was repeated every hour up to 8 p.m. At 10.15 p.m. he was drenched with sweat, and had a temperature of 99·3. On the 19th the temperature was 99.6. On the 20th, 21st, and 22nd about 100. On the 23rd the evening temperature was 99·6. On the 24th it was 99·1; after 4 p.m on this day he had three doses of ten grains of salicylic acid in the evening. On the 25th the temperature was 100; salicylic acid was given in ten-grain doses every second hour. On the 26th the temperature was 101; and on the 27th it was 100. After this the patient's health declined, and on July 6th he was seized with pericarditis with effusion, which carried him off.

Literature.

ELECTRICITY IN MEDICINE AND SURGERY. (a)

DR. POORE has produced that which was needed by the profession, a compact and yet thoroughly useful treatise on a subject of increasing importance. Some of the larger treatises were too large for the general readers and the smaller works were insufficient.

He adheres to the usual nomenclature, employing the terms Galvanism, Faradism, and Franklinism for the three kinds of medical electricity. The three first chapters contain the elementary matters, the principles and laws of electricity, descriptions of the more useful forms of apparatus; the author confines himself (and relieves the reader by doing so) to noticing such batteries and coils as are now most approved. The physiology of the subject is rendered in a practical manner.

(a) "Electricity in Medicine and Surgery." By G. Vivian Poore, M.D. Lond., M.R.C.P., Assistant Physician to University College Hospital, &c. London: Smith, Elder, and Co. 1876.

The author favours the Leclanché element, which is now made in a very compact form, a square cell about 1½ inch square by 4 inches high, divided by a porous septum placed diagonally, and covered in at the top, apertures being left for putting fluid in, and for the escape of gas. The zinc rod is placed in one compartment in a saturated solution of sal ammoniac, and the carbon rod is placed in the other surrounded by mixed carbon and peroxide of manganese.

This wonderful combination requires no attention for years, except the occasional addition of some fluid; it does not waste when out of use; but the current begins to flow directly the conductors are applied or the circuit closed. Unfortunately the necessarily good construction, and the fact of the battery being patented, cause the apparatus to be expensive. And the expense of the battery will be a lasting obstacle to the use of the continuous current.

The difference of action of galvanic and faradic currents is briefly but clearly given in the physiological chapter, which also contains much that is interesting on the subject which Dr. Poore has thrown new light upon—viz., fatigue of muscle removable by the continuous current. In order to represent this numerically, Dr. Poore employs a dynamometer which records the "squeezing" force of the hand—having made a number of trials of the patient's strength unaided—the author applies rheophores to the median nerve at two points in the upper arm, and causes a second series of trials with the dynamometer to be made. The averages of the sets of experiments with and without galvanism are then compared. In an experiment on himself, the author found that the galvanic current enabled him on the average to exert 11lbs. more squeezing force than he could apply without help. This chapter ends with a notice of Dr. Radcliffe's "positive charge."

The next chapter ("Methods of Using Electricity") is most practical, and contains several hints which the practitioner will value; among these the author describes an American rheophore, which has its conical piece of sponge fixed by its base to the wooden handle (without any metal cup).

There is a simple experiment by which it is possible to exhibit the production of electrotonus, and at the same time to disprove the prevalent idea that the *descending* current has greatest influence in stimulating motor nerves. "Place the positive pole in the axilla, and the negative over the ulnar nerve; we stimulate the ulnar nerve and get contraction of the muscles supplied by it. If we reverse the current (the negative pole in the axilla) we get much more movement—all three cords of the brachial plexus are stimulated, the arm is flexed, the hand supinated." Of course this does not prove that the ascending current is *stronger*, but its physiological action in this instance makes its muscular stimulation more extensive.

This chapter on Diagnosis is comprehensive, and should convince all who read it of the value of electrical apparatus in the *investigation* of disease.

The medical uses of this agent are described under the heads of Stimulation and Sedative Action. Very necessary cautions are given against employing galvanism or faradism in cases of recent central lesions, and other cases are indicated in which it is best not to use electricity. Illustrative cases of traumatic, infantile, and facial paralysis are given, to show the mode of using galvanism in these affections, the perseverance often needed, and the amount of success to be expected. We can confirm the author's statements as to the beneficial effects of galvanism in "rheumatic" paralysis.

Some interesting cases of local paralysis (*e.g.*, palsy of serratus magnus), of syphilitic and hysterical paralysis, rheumatic gout, amenorrhœa, skin disease, diabetes &c., are found in this part of the work, which is thereby rendered more readable than is often the case with chapters on electrical therapeutics.

The late Dr. Anstie's opinions on the use of galvanism in neuralgia are largely quoted in the chapter on Electricity as a Sedative.

Occipital neuralgia yields reluctantly, but costal neuralgia, periodic headache, lumbago and brachialgia, seem to be often rapidly cured by the continuous current.

The best passage in the whole book is that which relates to the pathology and treatment of fatigue diseases, writer's cramp serving as a typical form. After discussing the causes of *fatigue*, such as "monotonous repetitions of the same act," "prolonged and sustained muscular effort," "prolonging our periods of tension at the expense of the periods of relaxation," &c., the author gives the opinions of distinguished observers as to the nature of writer's cramp, those of Dr. Zaradelli of Pavia being the most elaborate. Dr. Poore analyses the act of writing, showing how complex it is, and therefore at how many points the writer may break down—the break-down may occur where it will—if only the first dorsal inter-osseous muscle fails, the act of writing immediately ceases to be automatic. "The patient becomes conscious of his troubles, and the disease is sure to spread rapidly." After giving directions for the examination of the patient, by touch, sight and electricity, the author describes his mode of treatment, which consists briefly of abstinence from writing, rhythmical exercise, and galvanism. Cases of torticollis and chorea successfully treated by galvanism conclude this section.

"Electricity as a Caustic" "as a Cautery," and "in the Treatment of Internal Aneurisms," form the subject-matter of the last three chapters. The peculiar apparatus needed for these applications of the galvanic current are described, and cases of aneurism with good and bad details are given.

All things considered, this is the best work on the subject that we have yet seen; the title-page well says that it is for "students and practitioners." Good illustrations are introduced where they are required.

◆

THE LATE DR. E. A. PARKES.

On the 18th inst. a public meeting in aid of the memorial fund was, by permission of the Council, held at University College, Gower Street. Sir William Jenner presided, and among those present were Mr. Erichsen, Dr. Reynolds, Dr. Sieveking, Dr. Sibson, Dr. Wilson Fox, Dr. Hare, Dr. G. Hewett, Mr. J. Marshall, Mr. Berkeley Hill, &c. The chairman, in opening the proceedings, called attention to the meeting held on the 10th of April at the residence of Mr. Erichsen, at which it was resolved "to establish at University College, London, a permanent memorial of the late Dr. Parkes, in such a form as to aid scientific investigation and practical study in the subjects to which Dr. Parkes's life was specially devoted." The memory of Dr. Parkes was, he said, too deeply engraven on the hearts of those who knew him to require any momorial, but they were anxious to show those to come the high appreciation in which he was held. It was therefore proposed to establish a memorial to him, and to have it in University College, where his education was altogether effected, where he made himself known to the world, and so distinguished himself as to be selected for the posts which he subsequently held [member of the Medical School and of the Senate of the University of London; Professor of Hygiene in the Army Medical School, Netley; Professor of Clinical Medicine at University College, London; and Physician to University College Hospital]. With reference to the form which the memorial should take, he again quoted from the above-mentioned resolution, and observed that Dr. Parkes's life, although not long, was devoted to several subjects, but particularly to two, clinical medicine and hygiene. The foundation of his hygienic knowledge was in clinical medicine, and, therefore, it would be proper to establish a memorial connected with clinical medicine. He thought, however, it was felt by others—and he shared the feeling—that, although Dr. Parkes devoted a considerable part of his life to clinical medicine, the crowning labours of his life were devoted to hygiene, he feeling more and more, with growing experience as they all did, its value and its importance in preventing disease, to which object he brought all his vast knowledge of clinical medicine. Quoting from the circular which has been sent out, he said it was hoped a sufficient sum might be collected "to establish a museum and laboratory of hygiene similar to those now existing in the Army Medical School, Netley;" but he thought part of the hope—as regarded the laboratory—was fulfilled to some extent by the large laboratory attached to the College. As to the museum it would contain all the materials connected with the progress of hygiene. An objection had been made to the establishment of such a museum, and it had been said that medicine was especially the centre of hygiene; but he was in favour of the museum, which he thought would be a very useful adjunct to the College, and a most valuable memorial to Dr. Parkes. In order that it might be a permanent memorial, however, it must be endowed. otherwise it would be perfectly worthless, and he should be absolutely opposed to establishing anything like a museum unless a sufficient amount were collected. Dr. W. R. Gowers then traced the origin of the movement, and after reading letters from Miss Florence Nightingale, Dr. Aitkin, Sir William Gull, &c., in its favour, he announced, amid cheers, subscriptions amounting to £675. Dr. Poore then detailed information he had acquired at Netley and Brussels relative to museums of hygiene. On the motion of Dr. Reynolds, seconded by Dr. Corfield, it was resolved that the memorial should take the form of a museum of hygiene. Dr. Sieveking, in moving the appointment of an executive committee, spoke of the importance of rendering the science of hygiene a permanent subject in the course of study of educated physicians. Mr. Symonds, of Oxford, seconded the resolution, which was carried, unanimously, Sir William Jenner being appointed chairman. The proceedings then terminated with a vote of thanks to the Chairman.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 26, 1876.

MR. GLADSTONE ON MEDICINE.

THE admirable speech which Mr. Gladstone has recently delivered at the London Hospital on Medical Education is remarkable for the complimentary tone in which he spoke of the medical profession, as well as for the original and philosophic view he took of the aims and aspirations of modern medicine. It is at all times gratifying to us to receive the approbation of those who, free from the prejudices and the complacencies by which most professional men are apt to be biased, can view from a more elevated standpoint the work we do, the means at our disposal, and the obstacles which lie in our path; and we feel the compliment all the more when it comes from a man whose experience of men and things is as great as his learning is extensive and his judgment matured.

Mr. Gladstone illustrates his opinion of the state of medical science at the present day by referring to a passage in "Gil Blas" with which most of our readers are no doubt familiar. He was not afraid, he said, to measure the change which had taken place in the position of the medical profession to remind them of one of the many excellent jests in one of the most entertaining of novels namely, where Gil Blas, arriving at a provincial town, fell seriously ill, but happily, the place was so small that it could not support a physician, and therefore he rapidly recovered. That, of course, was a joke, and a parody of the real state of things at that time. But what, adds Mr. Gladstone, would they think of a novelist who put such a jest into his book nowadays? Why they would say that unless the rest of the novel was made of much better materials than the sentence that contained that joke, the sooner he gave up novel-writing the better. In truth, though this profession was so ancient, and its use so vital, it was only in times comparatively modern and recent that it had made its way to general confidence. It had made its way to that confidence not by having mastered the secrets of disease . . . but because the world was well aware that the very highest of human abilities were addressed, and addressed in ample quantity, to the business of this profession, and that these abilities were addressed to it with all the zeal and all the judgment which they could expect from human capacity and assiduity in any of the pursuits of life."

It is quite certain from this and other passages in his speech, that Mr. Gladstone does not look forward to that advanced state of medical science, and that improved condition of the public health so sanguinely expected by what we may, for the want of a better term, call the hygienic school of medicine; and it is only in this respect that we shall venture to differ from the opinions which he has expressed in his otherwise unexceptionable speech, and to hope that the picture which he gives us of the future of medicine and of public health will not, when realised, be quite so gloomy as he forecasts. The mastering of the secrets of disease is a progressive work, and for his own part, Mr. Gladstone believed that it never would reach that point; and that probably, in the future experience of society, as we detected disease in one form and one development, new forms and new developments would arise which would continually baffle our efforts in the way of making advances. He "was impressed with the belief that, as the organisation of society and the structure of life had become in modern times greatly more complex than they were, so the process of evolution would continue, and from generation to generation the probability was that life would become still more complex, and its griefs and enjoyments would be still more multiplied. Man's subserviency to luxuries and pleasures would also increase, together with its attendant difficulties, and man's dependence on the help that the physician could afford would likewise grow. In proportion as man's enjoyments increased, so would his sufferings and the necessity for help to assuage them."

Now, although we would not go so far as to subscribe the optimist views of some eminent hygienists, we certainly have a more cheerful prospect of the future state of medical science, and of the physical and moral welfare of future generations of mankind, than that implied in the opinions which we have just quoted. No doubt, there are diseases in the intimate nature of which we shall never thoroughly comprehend. The cry that is even now being raised against one of the most beneficent prophylactic discoveries of modern medicine forbids us to look forward to the time when the good sense and the self-command of society will allow it to take full advantage of the benefits which science has placed in its hands; while a still longer time must elapse before we shall see the last of the many diseases that depend upon the habits, the desires, the appetites, and the passions of mankind.

But, on the other hand, the history of medicine, in fact, all history, tells us we may presume to rest our claims upon the confidence of the public, upon even better grounds than upon the "high abilities" which are addressed to the duties of our profession; while, at the same time, it gives us little reason for supposing that the human race will be harassed by new forms of disease as fast as old forms disappear, or that the trials and the miseries of life will be more complex and more multiplied in proportion as its luxuries and its enjoyments increase.

The history of medicine, like many other great histories, is by no means such as we can look back to with unmingled satisfaction. It has been a very chequered history, and has been marred by an amount of ignorance and superstition which we cannot now contemplate without a feeling akin to shame. But for all that, a retrospect of the last two hundred years shows that our knowledge of the principles and practice of medicine has made rapid and substantial progress; and that in every department of that science, in diagnostics, in pathology, in therapeutics, in hygiene, we both know, and can do more now than ever we knew or could do fifty years ago. We need not enlarge upon this fact, inasmuch as it is one that is very generally admitted, and our only reason for stating it is, that it offers the strongest grounds for believing that in the course of time still more may be accomplished, and, that this very advancement may be, in the hands of Providence, one means by which the future comfort and welfare of mankind will be proportionately advanced. When hundreds of years ago great minds did not despair when they looked into the future, surely we can still be more hopeful in an age so richly endowed with knowledge, and in an age when the comforts and arts of life are so immeasurably greater than they were in former times. More than 2000 years ago that dreadful disease epilepsy was looked upon in the most civilised portions of the then known world as a direct visitation of the gods, against which it was useless, and even impious, for man to contend. But the immortal Hippocrates was neither so blinded by superstition, nor so distrustful as to the power of his art, as to share in the opinions of his countrymen. A glimmer of light appeared to him in the distant horizon, which he thought would one day grow brighter and dispel the darkness in which the nature and treatment of that disease were in his time enveloped. He fearlessly asserted that epilepsy was no more a divine affection than any other, that it arose from causes which would one day be revealed, and was amenable to remedies that would be discovered in the course of time. We pass over a few centuries, and we come upon another undaunted spirit—the immortal Harvey, who, like the father of medicine, found himself confronted with a problem which he almost thought to be incapable of solution. "Devoting myself," he says, "to discover the use and utility of the movement of the heart in animals, in a great number of vivisections, I found the subject so full of difficulties that I thought for a long time, with Fracastor, that the secret was known to God alone. . . Finally, from redoubted care and attention, by multiplying and varying my experiments, and by comparing the various results, I believed I had put my finger upon the truth, and commenced unravelling the labyrinth." Since that time many other secrets have been arrested from nature. We have placed our finger upon many truths, and made discoveries which have had a marked effect in investigating human suffering and in prolonging life. And who can at present gauge the limits of medical discovery, or the limits which Nature has assigned to the physical and social well-being of the human race? If pain has in many instances been abolished, if we can now cure diseases which were formerly regarded as incurable, if we can now restore to her family the mother who was, not so long ago, devoted to an early grave, if one of the greatest scourges of mankind is now but seldom heard of, if certain epidemics are as now all but under our complete control, and if in many places the average mortality is far below what it formerly was, while human longevity is on the whole increased—what may we not hope for if we only look far enough into the future. And at all events have we much reason to fear that the secrets of diseases which are now obscure will never be unravelled, that disease and misery will keep pace with "the increase of man's estate," and that man will become more and more dependent upon the help that physicians can bestow. Rather may we say with an eminent living writer: "Products of the mighty past, we forefeel dimly, as it were, the mighty future of humanity."

Space will scarcely allow us to notice the other subjects on which Mr. Gladstone so eloquently discoursed, suffice it to say, that his remarks should receive the closest attention of all who are about to enter the profession. Especially valuable are his observations upon that "besetting danger of this age—specialism," and upon the influence which the wise and philosophic physician may have over the speculative thought of the present day. "In this activity of speculative thought," said Mr. Gladstone, "which had undoubtedly reached a point in this age which they were not aware of in former times, he could not help seeing that an opportunity was given to the medical profession to exercise increased influence, and assume a greater share in the leadership of thought at large." We believe we shall not be far wrong in saying that the profession has already accepted this responsibility, and that it has already diverted the current of speculative, especially metaphysical, thought into a wider and more useful channel. The peculiar nature of their studies, and the discipline which their mind has received from a scientific education, have led medical men to repose little confidence in theories that are unsupported by facts, and to conduct their investigations on the most approved principles of the inductive philosophy.

THE VIVISECTION BILL.

It was currently reported during the week that Government had positively decided upon the withdrawal of the "Vivisection Bill," but we gather from the Prime Minister's answer to Mr. Lowe, and also from the Home Secretarys' reply to a deputation that this is not exactly the case. If, however, Mr. Cross is sincere in his statement, that the Government are in no way likely to be influenced by passionate appeals, but would act from a common sense view and without prejudice, it scarcely admits of a doubt, that the Bill will at once give way to a number of other Bills of far more importance to the country. Why should this crude and ill-considered bantling, framed at the bidding of a set of unreasonable and sentimental fanatics, be allowed to drag on with the annoyance of a painful uncertainty about its existence, and simply to be abandoned with a bad grace a week or two hence? The Government must be convinced that it was a grave mistake to have introduced a Bill which has brought them into difficulties and made them far more enemies than friends. No good can come of hurried legislation on a subject which requires delicacy of handling and careful consideration. If, unhappily the Government should be still induced to listen to the unwise solicitations of unreasonable people, who have hitherto shown themselves miserably deficient in argument and totally unable to understand the question at issue, then it only remains for Mr. Lowe and other members to make a resolute effort to throw out a Bill which Mr. Lowe very rightly says gives "any person the right to inflict any pain short of torture on any domestic animal, and any torture he pleases in any non-domestic animal; and it is a gross insult to the medical profession to single out as the only exception to these general rules."

A meeting of the Metropolitan Counties Branch of the British Medical Association is convened for this evening, at 8 p.m., at the Medical Society's Rooms, Chandos Street, at which the following resolutions will be proposed:—

1. "That this meeting, although fully recognising the improvements effected in Lord Carnarvon's Bill in its latest form, is still strongly of opinion that should it become law the progress of science will be most seriously hindered, and the interests both of animals and of men much prejudiced.

2. "That this meeting would urge upon the promoters of the Bill that legislation on this subject should be abandoned for the present session.

3. "That, in the event of its being thought necessary to propose legislation on this subject in the future, this meeting would suggest as alternative measures—(1) an Act of simple registration of persons licensed, as on the plan of Dr. Lyon Playfair's proposal; or (2), which would be preferable, an Act in extension of Martin's Act, applicable to cruelty of all forms to all animals, but exempting, under certain conditions and regulations, experiments performed solely for the advancement of science."

At a special meeting of the College of Physicians of London last week the Bill was discussed and the president and censors were appointed to wait upon the Home Secretary and to express the great objections of the College to the Bill. A memorial has also been presented to the House of Lords by the University of Edinburgh, in which it is conclusively shown that the Government Bill would foster rather than check cruelty; and that to "crib, cabin, and confine" the labours of physiologists to a few licensed places would be to cripple and stop all scientific investigation, for very many of the most valuable experiments have been performed by men who were not professed physiologists. Surely it will not be considered politic for the British legislature to dictate to the profession how it shall acquire the knowledge of curing disease.

◆

THE CONTAGIOUS DISEASES ACT.

The nation (and notably the ladies who insisted on forcing themselves into the gallery of the House) have been edified by the annual discussion of the Bill for the propagation of syphilis and gonorrhœa, known in Parliamentary parlance as the Contagious Diseases Act Repeal Bill, and we sincerely trust that the nasty and unprofitable controversy may be considered as got rid of for twelve months at least. The result of some years experience of the working of the Act and of the benefits derived from it, has been to narrow the debate to a contest between puritanism and expediency, for, in spite of the clamorous assertions of the Anti-Contagious Diseases Act fanatics, it may now be taken as proved beyond any reasonable doubt that the outcome of the present law has been a great and lasting gain to the public services and to the community. The opponents of the present system have, indeed, utterly failed to disprove or to account for the immunity of the army and navy from venereal diseases which has ensued since the Act came into operation, and the attempts they have made to do so have only served to strengthen the conclusion that the supervision of prostitution in camps and garrison towns has produced, and may be expected to continue to produce, the best results upon both the health and the morals of soldiers and sailors, and of those classes of the civil community with whom they are associated. Appropriate to the discussion of this question we publish to-day, in a communication on Salivation by Dr. Rawdon Macnamara, of Dublin, Surgeon to the Lock Hospital, what may be called the calendar of a prostitute, and which we reproduce for more public observation here. Speaking of the subject of his treatment Dr. Macnamara says:—

The results as to her history, so far as the hospital statistics go, are embodied in the following tabular statement. I may state that her age when she came under my observation was twenty-seven years.

	Admitted.	Discharged.	Days in Hospital.	Disease.
1872	Dec. 16	Dec. 21	5	Sore at labium.
1874	Jan. 19	Jan. 22	4	Double iritis.
1874	Feb. 17	March 11	23	Papular rash; iritis.
1874	Aug. 31	Sept. 25	26	Ulceration of throat and of back.
1875	Jan. 12	Jan. 22	11	Patches in mouth and vulva.
1875	March 1	March 19	19	Extensive ulcer on vulva.
1875	June 2	June 22	21	Stomatitis (severe).
1875	June 23	July 8	16	Profuse salivation.
1875	Aug. 2	Aug. 19	18	Ulcerated throat; abscess in axilla.
1875	Oct. 4	Nov. 12	40	Severe ulceration and salivation.
1876	Feb. 7	Feb. 16	10	Ulcerated mouth and throat (patch).
1876	April 3	May 6	33	Salivation.
1876	June 9	June 20	12	Gonorrhœa; bubos.

A simple perusal of this table must give rise to many melancholy considerations. It is simply deplorable to find that one so young should have led so wretched a life—a life as full of disease as it was of sin. To understand the table fully, a few words of comment are necessary. When first admitted, she appears on our books as being a married woman—aged but twenty-three years. Of the fact of her being married, there can be no doubt, as, by the rules of the institution, to be admitted as such, she must produce her marriage certificate. Between December, 1872, and January, 1874, we have no record of her having been under treatment, at the Lock Hospital, at all events—then comes the history of secondary contamination—and of fresh infection. From March the 1st to March the 19th she was under treatment for an "extensive ulcer on the vulva," the treatment as appears from our books being local and constitutional, the latter consisting principally of tonics, opium, and good diet. She then leaves the hospital, and, as we collect from her own statement, during the period which elapsed between the 19th March and the 2nd of June, she is put on mercurial treatment elsewhere, and returns to us with the first appearance of what subsequently proved so intractable a form of ptyalism.

It will be seen that this woman in three-and-half years of her life of prostitution was in and out of hospital thirteen times, during which period she spent 238 days under treatment, or one-fifth of the whole time. During the remaining four-fifths of the time she was doubtless engaged in the assiduous dissemination of chancres and bubos, many of which will have probably been passed on to innocent recipients and to families of unborn children. The fanatics who oppose the enactments which have been framed to protect the innocent community from the effects of so horrible a trade, will be sanguine indeed if they entertain any real hope that they will persuade deep thinkers that such a traffic should be permitted to proceed without check or control simply because in their opinion it is better not to pretend to know of its existence or to recognise the class of persons who are engaged in it. The Anti-Contagious Diseases Act advocates have not the discernment to distinguish between practical morality and stupid puritanism, nor the common sense to bend their tightly strained notions of right and religion to meet the crying necessities of the community.

◆

SURGICAL AID FOR THE TURKISH WAR.

It appears from a communication to the *Standard* from Mr. C. Roberts, surgeon, that since his publication in that paper of a letter on the above subject, he has been overwhelmed with offers of surgical assistance, but that he has received few expressions of sympathy outside the profession. Mr. Roberts advises those of his correspondents who do not object, to give their services to the League in Aid of the Christians in Turkey, who have within the last few days established a Servian Hospital Fund. They must bear in mind, however, that they will be liable to share the fate of rebels if they fall into the hands of the Turks. The League's Hospital Fund may serve to relieve the immediate wants of the Servians, to which public attention was first called by one of our foreign correspondents. But Mr. Roberts remarks that the political sympathies of this country are too greatly divided to give it much support : that the revival of the Red Cross Society, which would distribute aid to the wounded irrespective of creed or race, would alone meet the present emergency ; and that there is just now a large number of surgeons and dressers ready at any moment to give their services to either Christians or Turks.

This is not holding out a very charming prospect to those younger members of our profession whose enthusiasm might lead them to risk their lives in what might probably turn out an unprofitable and thankless service. "To be liable to share the fate of rebels if they fall into the hands of the Turks" is no trifling matter. It might mean being butchered by a class of men little better than savages. An English surgeon is never wanting in the courage and bravery belonging to his race. To die sword in hand, and fighting in a good cause—to die in the heat and excitement of battle—is one thing ; to have your throat cut while quietly practising a humane and charitable profession, is quite another matter. During the Crimean War, we had the opportunity of accompanying a regiment of Bashi-Bazouks, and of making a personal acquaintance with some of those irregular troops by which both the Servian and Turkish armies are so largely recruited, and a more untrustworthy and desperate set of men we have never seen, so that we are not at all surprised at the atrocities which are now said to be committed by them in Bulgaria, and which, although possibly exaggerated, we do not for a moment hesitate to believe in. We must, however, own that in Turkey, as in most semi-civilised countries, the surgeon is treated by those who know him with great reverence and respect, and even when living amongst these Bashis—these half soldiers, half banditti—we believe they would at any time have risked their lives for us. If, therefore, the Red Cross Society could be revived in that now distracted country, and its position and objects duly recognised by both parties irrespective of creed or race, much might be done to mitigate the horrors of a war carried on in such a half-civilised country as Turkey. Besides, it is not merely against the ferocity and fanaticism of the Servians or the Turks that the young surgeon would have to contend, but against obstacles arising from a probable scarcity of all those surgical appliances, medicine ambulance, medical comforts, &c., without which his services could neither be advantageous to the wounded nor profitable to himself.

We are therefore inclined to suggest to surgeons intending to set out for Turkey that they should carefully consider the step they are taking.

While writing the above, we hear that two English surgeons—Mr. Baker and Mr. Collingridge—arrived at Belgrade last Wednesday, and left soon afterwards for the army before Novi-Bazar. All we can say is that we shall be glad to hear of their safe return, and that in the meantime they will not fall into the hands of our old friends, the Bashi-Bazouks.

Notes on Current Topics.

Butter Manufacture and Adulteration.

The head of the Chemical Laboratory of the Board of Inland Revenue reports on a series of butter analyses lately made by him, that of the 107 samples examined and tested, only a very few were very poor in quality. The great bulk examined were found to possess considerable uniformity of composition, the principal variations being apparently due to a difference in the method of manufacture, the different seasons of the year when made, and the various modes of feeding. As might be expected, some of the poorest butters were produced by, and obtained from, small farmers in Ireland, at a time when there was very little grass and food was scarce. It was also noticed that the butter was relatively poorer in its essential constituents when the food was chiefly cotton and oil-cake, than was the case when roots and grass formed the staple food. A noticeable feature in the results recorded is the great variation in the quantity of water in the different butters, the lowest being 4·15 per cent. and the highest 20·75 per cent. The Devon and Dorset butters, which usually stand so high in the market, were found to contain in nearly all cases a high percentage of water, and one which was procured from the dairy of a private gentleman contained as much as 16·99 per cent., and a second sample, recently obtained from the same source, contained 15·70 per cent. Another point of interest was in some measure elucidated, and which has reference to the deterioration which certain butters undergo when kept in small quantities in glass or earthenware vessels. It was found that whilst some of the finest and best prepared butters undergo little or no change, there is in others a gradual disappearance of the characteristic principles of butter, and a consequent assimilation to the constitution of an ordinary animal fat. This change, which appears to be due to an incipient fermentation, and is generally accompanied by the development of fungi, is probably caused either by the use of sour cream or by insufficient care in making butter.

The Plague.

DR. THOLOZAN informs us that various sanitary measures have recently been adopted by the Turkish and Persian Governments with reference to the outbreak of plague, which commenced in Mesopotamia in the early part of the year. Since the beginning of March a sanitary *cordon* has been established on the north of the invaded territory, on the most frequented route of Kurdistan and Syria, between Tecrit and Kifri. On the south a quarantine of fifteen days is obligatory since April 1 on all vessels sailing on the Tigris and the Euphrates. It is at Kourna, at the confluence of these rivers. The ports of the Persian Gulf are protected by a quarantine which vessels from infected localities have to undergo at the island of Kezzer, formed by a junction of the Chotel Aral and the Karoun. Since April 10 all communications by land between Persia and Mesopotamia are subject to a quarantine of fifteen days. For three years, it may be added, all pilgrimages into the infected country by Persian subjects have been interdicted. To fully comprehend this system of protection it should be remembered that on the west and north-west, for an extent of three degrees of latitude, no artificial barrier has been or can be established against the plague; but there are, happily, natural obstacles, which prove much more efficacious, the infected region being there bounded by the deserts of Syria and Mesopotamia. The greater rarity of communications there renders restrictive measures, on the arriving caravans, easier. Judging from past outbreaks of plague, it was anticipated that the present would decline in June (after reaching its *acmé* in the end of May), and disappear from Mesopotamia in July. But it may send offshoots to Bussora, Bouchêre, and Arabistan, and a still greater danger is the introduction of germs of the plague into the high plateaux of Anatolia, Kurdistan, and Persia. It is stated upon reliable authority that the disease is rapidly decreasing; but there cannot be the slightest doubt that at Bagdad they have had a visitation of the true plague in its worst form.

Royal Hospital for Diseases of the Chest.

THE authorities of this hospital were fortunate in enlisting the sympathy of H.R.H. the Princess Louise, who so graciously undertook the duty of laying the foundation stone of a new wing on Wednesday last. It is not generally known that this institution, which is situated in the midst of one of the most densely populated districts of London—that of Clerkenwell—was the first in the United Kingdom, if not in Christendom, especially founded for the study of pulmonary diseases, and the reception of patients suffering therefrom. In performing the ceremony last week, which, when the work is completed, will give the medical staff sixty beds extra, H.R.H. was surrounded by a brilliant company, and the purses presented were both numerous and valuable. After going through the wards, under the conduct of the medical staff, a prayer for the success of the undertaking was offered in one of the spacious tents erected for the occasion, and the stone duly laid. Shortly after H.R.H. took her departure amidst every manifestation of loyalty and gratitude for the act performed.

The Simon Memorial.

THERE appears to be a rush of testimonials and memorials to members of the profession, or to deceased ones just now, which we think both unwise and unfortunate, inasmuch as one necessarily interferes with the success of another, and neither receives that measure of support to which its individual claims entitles it, and which it would undoubtedly receive were it *alone* under the notice of the profession. Thus we have at present the Parkes memorial, the Harvey memorial, the Hassall testimonial, the memorial to Sir J. Cordy Burrows, and now it is proposed to start a Testimonial Fund to Mr. Simon, C.B., F.R.S., late medical officer of health to the Privy Council and the Local Government Board, in recognition of his eminent services in sanitary science. In furtherance of this object, a committee of medical officers and others has been formed, and the co-operation of persons interested in sanitary work is invited. It is proposed that the testimonial shall take the form of a Scholarship and Medal; but suggestions on this point are invited of subscribers. Mr. Alfred Haviland, medical officer of health for Northampton, has undertaken to act as hon. secretary to the committee.

The Social Science Congress of 1876.

THE annual meeting of the Social Science Association will be held at Liverpool in October next, at which the following special questions for discussion in the health department will be introduced:

1. What is the best mode of making provision for the supply and storage of water (1) in large towns, such as Liverpool and Manchester; (2) in groups of urban communities of lesser size, such as exist in the manufacturing districts of Lancashire and Yorkshire?

2. What further legal enactments, if any, are required with a view to arrest the spread of infectious fevers, and

how far national and municipal registration is desirable as a means thereto, and if so, what should be the nature of such registration?

3. What amendments are required in the legislation necessary to prevent the evils arising from noxious vapours and smoke.

Mason *v.* Fergusson and others.

THE late trial, Mason *v.* Fergusson and others, the object of which was to overthrow a will on the ground of insanity, the plaintiff's Christian name was Francis. Not unnaturally the profession and the public supposed the plaintiff to be Mr. Francis Mason, of St. Thomas's Hospital, and formerly assistant-surgeon to King's College Hospital, and colleague of Sir Wm. Fergusson.

The mistake has given rise to some considerable annoyance to our *confrère*, and it is our desire to make it generally known that he (the plaintiff) referred to, though bearing the same name, are unknown to each other, and in no way related.

Eau de Vie.

MESSRS. HENRY BRETT and Co. have introduced a spirit in imitation of the best French brandy, just as London gin is an imitation of Schiedam Hollands. It is made with rectified spirit, and contains therefore no objectionable taste or essential oil, whilst it is well known that many of the compounds sold as brandy in London contain essential oils, which produce headache and restlessness, and otherwise interfere with the digestive functions. The London gin is now perhaps the most frequently used of all the spirits, notwithstanding that it is an imitation, often an injurious one, of a genuine spirit. It is our principle to advise abstinence from all spirits except when prescribed therapeutically, but we suggest that when people are about to purchase the cheaper compounds known as brandy, many of which contain injurious matters—they will do well to obtain instead this eau de vie, the purity of which is guaranteed.

The Metropolitan Water Supply.

DR. FRANKLAND reports that his chemical examination of the water supplied to the metropolis during the month of June show it to be of an improved quality. That from the Thames and Lea has now assumed its summer quality, and contains only about one-fourth as much organic matter as it did during the worst winter floods. The water was all delivered in an efficiently filtered condition, except that of the Southwark Company, which was slightly turbid and contained numerous moving organisms. The Kent Company's water was clear, brilliant, and wholesome. The highest temperature of the Thames water taken at Seething Wells was 69°, and the lowest 56°, while the highest temperature of the air at the same place was 83°, and the lowest 56°. The Kent Company have extended the constant supply in their district in pursuance of the provisions of the Metropolis Water Act, 1871, and are now giving constant supply to a considerable portion of their districts. The New River Company is, it appears, engaged in the sinking of a new well into the chalk formation at Turnford, to obtain at that place a fresh supply of [illegible] a large boring into the lower green sand. This [illegible] was commenced at the beginning of 1874, and it has now reached a depth of 740 feet from the surface. To provide for the increasing demands of their district, the Company are making additions to their distributory works, to effect the separation of the very different levels of their service into convenient zones, and to add to the power and means of communication by which their different stations are enabled to assist one another.

Sir Wm. Gull and the Bravo Case.

THE profession and the public will have followed the details of this mysterious case of poisoning with much interest, and many points have arisen which put to the test cardinal rules of action for medical men and friends when under circumstances in which the possibility of poisoning by accident or otherwise may have to be reviewed without much time for deliberation. Taking the very careful report which appears in the *Times* of July 15, it would appear that Sir William Gull is about to establish a new precedent for the conduct of consultees. The precedent, moreover, is one which we think will not meet with the sanction of the profession generally, and will not be conducive to the public interest if followed by other consulting physicians. Quoting from the *Times* of July 15, we find the following report:—

"I found the gentleman in bed, pulseless, but quite mentally coherent. After examining him a minute or two I said to him, 'This is not disease,' or words to that effect, 'you are poisoned,' or 'dying of poison,' I would not be sure which—'pray tell me how you came by it?' . . . I then urged him as solemnly as I could to tell us, &c., &c."

Subsequently, under cross-examination by Mr. Gorst, Sir William explains:—

"I think," added Sir William, "that the Court should know that in a case like this, in which I, without retiring to consult my colleagues, upon my own responsibility entirely, told the dying man at once that he was poisoned and was dying, I took upon myself a grave responsibility, and under such important circumstances things may be said or done which may escape the notice of one so engaged as I was. You must remember, too, that I was taken to see a man in disease, and I found, not a case of disease, but a case of poison, &c."

Now, when we recall the fact that in addition to Mr. Royes Bell and other gentlemen engaged in the case, Dr. George Johnson was actually standing by the bedside, it is difficult to see how a course so extraordinary as this can be justified on the part of one of our leading consulting physicians. Not only is the precedent thus set by Sir William in direct violation of the bye-laws regulating the conduct of members of the Royal College of Physicians, not only was there no instant urgency to justify such a violation in this particular case, but the precedent is one which, we venture to say, would, if followed by other consultees, destroy that concert and that working harmony which is necessary for the correction of hasty impressions on the part of a consultee, and is indispensable to the welfare of the sick. Not the least extraordinary part of the narrative is the complacent egotism which makes Sir William appear to be unconscious of the unusual character of the course which he thus dilates upon. The whole thing is very much like the exhibition which Erskine, the great advocate, once made of himself when he appeared in the witness-box to give evidence on a matter of fact.

Local Treatment of Chronic Dysentery.

The following is an abstract of an interesting case noticed in the *Melbourne Medical Record*, but which originally appeared in the *New York Medical Journal*. The patient was a woman who had been suffering from chronic dysentery for five years, with occasional acute attacks excited by any indiscretions in diet or unusual fatigue. The smallest number of dejections daily during the whole period was eight, but it was not unusual for twenty-seven or more to occur. She had been under the care of many physicians and under various plans of treatment, and at the time the local treatment was begun she was in a "desperate condition of debility." Dr. T. Gaillard Thomas placed the patient in the left lateral position, and under an anæsthetic, and with the aid of a long duck-bill speculum and a retractor explored the whole of the rectum. On washing the mucous membrane it was seen "swollen, œdematous, hanging in hæmorrhoidal masses, and studded with deep ulcers with greyish bottoms, and it was of a deep red, almost violet hue." At a subsequent examination all the ulcers were lightly touched with commercial nitric acid by means of a swab of wet cotton on a whalebone rod, the cauterisation being so graduated as to avoid the possibility of any sloughing taking place. Only a little pain was experienced on recovery from the anæsthetic, and the patient declared afterwards that this treatment gave her the first real respite she had had for five years. Two other similar applications were made at the interval of a week each, and soon after she returned home, declaring herself well. Rest and milk diet were insisted on during the treatment.

This treatment originated with Dr. R. B. Maury, of Memphis, Tenn., who had treated twelve cases, eleven of which recovered. The caustic he used, however, was nitrate of silver, in strength from the solid stick to that of a solution of a drachm to an ounce of water. But with care to avoid such cauterisations as to produce sloughing, Dr. T. thinks there is no danger of rectal stricture from the use of nitric acid. In such cases caustic is beneficial not only in stimulating the healing of the ulcers, but in blunting the sensibility of the irritable rectum, thus restoring quiet to the whole intestinal tract.

Commission on Noxious Fumes.

We are glad to hear that in the House of Commons last Tuesday, Mr. Cross informed Mr. S. Lloyd that it was intended to appoint a commission to inquire into the effect of the emission of noxious fumes from certain manufactories, and a formal announcement of it would appear in that night's *Gazette*. It would be constituted as follows: Lord Aberdare (chairman), Earl Percy, Viscount Middleton, Mr. W. Egerton, Mr. Stevenson, Professor Abel, Professor Williamson, Mr. Roscoe, and Retired Vice-Admiral Hornby.

There cannot be a greater proof of the anxious attention that is now beng paid to the hygienic condition of manufacturing towns than the attempts that have been made from time to time to obviate the evil effects arising from the various operations carried on in many of our great manufactories. We look forward to a time when the health and comfort of those working or living in the neighbourhood of these establishments will be little short of that to be found in any other place.

The Vivisection Question.

Some of the correspondence which has recently appeared on this subject is well worthy of notice. "A Student of Medicine" writes to the *Times* to show, from his own personal knowledge, what care is taken at the hospitals not only to thoroughly narcotise the animal to be experimented upon, but to keep up the influence of the anæsthetic until the experiment is concluded or up to the time that the animal dies. His letter is well calculated to show "how utterly unfounded is the popular belief in the prevalence of cruelty in vivisection," but we are afraid it may give his readers the impression that this method of experiment or of demonstration is carried on in our hospitals to a much greater extent than it really is.

Much more telling are some of the remarks Mr. Erasmus Wilson has made in a letter which appears in the same paper. In reference to the observations of a previous correspondent, Bishop Claughton, he says :—"We are perfect as men, but—and here is the sting of the arrow—we are not to be trusted. We are trusted, universally trusted, and most unhesitatingly so, with the accidents of the birth, the health, and the decay of our fellow-men; but we are not to be trusted with the lives of the few animals required by our science for the attainment of that knowledge which is the source of the trust and faith reposed in us in our professional capacity. We have already been rudely handled by an authority which represents force; we are threatened with the inquisition of the Government policeman, or, in its mildest shape, with that of a Home Secretary who must be a very foreigner to the requirements of our craft. These are the matters of which we most justly complain; we ask to be left alone, and we protest against an interference which can only bring upon us humiliation and annoyance. But if, indeed, there be anything in our proceedings that may seem to require modification or alteration, we feel that we have earned a title to be consulted in such matters, and if consulted like men deserving of consideration and respect, I am sure I may answer for my brethren of the profession that we shall not be found unreasonable.

The Metropolis Water-Supply Act.

It is not generally known that this Act provides power to compel all the Companies to give constant supply as and when the public authorities may see fit to demand; and any district may insist upon a constant supply when and so soon as four-fifths of the district are provided with the proper fittings, in accordance with the Regulations made under the above-mentioned Act. We have never altered our opinion as to the value of a continuous against an intermittent supply; and in the present excessive heat it is all the more incumbent that water for drinking purposes should not be stored in cisterns, which are often in a filthy state, loaded with organic accumulations and infusorial life. Medical Officers of Health know too well that the lower classes are, as a whole, perfectly indifferent in these matters; it is for the profession and the thinking public to take the initiative; the law is in their hands, they must insist upon its proper execution.

Mercurial Poisoning from Tinned Meats.

At a recent meeting of the chemical section of the New York Academy of Sciences, Professor Falke stated that, on opening a can of cooked corn beef, put up by a company in Chicago, he noticed some bright metallic globules, which proved to be metallic mercury. Besides these, a considerable quantity of combined mercury was present in the form of albuminate of mercury. How the poison came in the meat is a mystery; but a member suggested that, inasmuch as thermometers are employed to regulate the temperature when canning, the mercury may have come from a broken thermometer. It may be interesting to note that a case of poisoning has been reported in Boston from eating canned cooked corn beef.

The Traffic in Quack Medicines.

An amusing case, yet one illustrative of the pseudo-medical system which obtains in the English provinces, has been tried at Stamford a fortnight since. The contest was to try the liability of an attorney at Gravesend to pay for the printer's puffing of the "Okamatuty Cough Lozenges," which were declared to be a medicament celebrated in the Stamford locality. It appeared that one, Fenwick, purchased the Apothecaries' Hall Company in Stamford for £1,000. Having no money of his own, he got £150 as a loan from the attorney in question, and gave a bill for £879 more, which, being dishonoured, was taken up by the attorney. The trade not paying, was shut up by the legal proprietor, who paid all the debts (thus incurring a loss of £1,000), except the printer's bill for puffs of the "Okamatuty," which he averred belonged to the druggist. Eventually the attorney had to pay this also, and the druggist has established himself as a dentist at Southend. Is there not something acutely British in the whole transaction? Could the system be matched in the whole world? The attorney in Gravesend "running" the druggist's shop in Stamford; the yokels of Stamford buying, and presumably eating, the "Okamatuty;" and, finally, the druggist in Stamford being transformed by bankruptcy into a practising dentist at Southend.

Vivisection in Germany.

Professor von E. Cyon has recently published the first portion of a very excellent Handbook for the Physiological Laboratory (*Methodik der physiologischen Experimente und Vivisectionen*), in which there are one or two passages which will show that Continental physiologists are not the brutes which some of our friends in this country have made them out to be. In the first chapter of the work we have several rules laid down for the performance of experiments on animals, two of which are as follows:—"1st. Never proceed to a vivisection without having first proved the impossibility of attaining the desired object (especially in demonstration) in any other way. 2nd. When not altogether inconsistent with the nature of the experiment, always produce a preliminary narcotization." The author concludes his excellent advice by saying: "Always operate on animals as if after the vivisection they were to be kept alive under the best possible conditions."

Another Miracle.

Under the above title the *Bordeaux Médical* tells a strange story, which shows how easy it is to get up a miracle:—About eighteen months ago a girl was admitted into the Hospital Saint André, at Bordeaux, for necrosis of the femur. From other complications that occurred the case did not turn out very satisfactorily, and chronic arthritis was gradually developed in the knee. An immovable apparatus was applied, and in four months' time the patient had so far recovered as to be able to walk about with the splints, and to perform the duties of a nurse. The splints were then removed, but occasionally reapplied, and in the course of four more months she was able to walk about the ward. About this time she got permission to visit some of her friends near Bordeaux, the surgeon thinking that she was nearly well, and would soon be able to leave off her splints. But instead of doing this, she goes to Lourdes; where, as she said on her return to the hospital, she felt herself suddenly cured. On further inquiry it was found that on her departure she had taken with her some crutches which she had formerly used, and that just before arriving at that celebrated place she threw them away, exclaiming that she was cured. Immediately there was great excitement among the pilgrims, cries of "A miracle! a miracle!" and in short, all the usual accompaniments of such religious revivals.

Indignant at the deception that had been practised, the surgeon of the hospital immediately dismissed the girl from his service. But the matter did not end here. The surgeon was accused of impiety, and of denying the facts of the miracle. The pretended miracle was published in a Roman Catholic review of this town (Bordeaux), and copied into a daily journal. The report spread everywhere, and now in all the departments they are speaking of nothing but of this new miracle. And what was at the bottom of all this imposture and credulity? A chronic arthritis of the knee-joint, cured by ordinary means, with anchylosis after eight months' treatment, and a miserable comedy played by an ignorant girl.

We may add that this artful hussy had, in order to carry out her designs, taken care to get cured before she left the hospital, and that, thanks to her lymphatic temperament, to the circumstances attending her illness, and to the occasional fits of syncope to which she was liable, this girl had all the qualities requisite to act the religious impostor. The whole affair is a caution to those who in this part of the world take in hand similar cases.

One and a quarter million gallons of cod-liver oil have been made in Newfoundland this season. It is worth on the spot about 3s. per gallon, and is shipped principally to England.

International Medical Congress at Philadelphia.

THE *New York Medical Record* mentions the following delegates among others:—From the Medical Society of Copenhagen, Drs. Edmund Hansen (President), Carl Lange, and S. Englested; from the Pathological Society of Dublin, Mr. Joliffe Tufnell and Mr. Wm. Stokes; from the Obstetrical Society of Edinburgh, Drs. Alexander R. Simpson (President), and Finlay. The following gentlemen are also expected:—H. Power, of London, J. A. Estlander, of Heslingfors, and Alfred Haviland, of London.

The following have been appointed to act as delegates of the Medical Society of London: Mr. William Adams, F.R.C.S., President; Mr. Richard Davy, F.R.C.S. Senior Secretary; and Dr. T. Lauder Brunton, F.R.S.

Injury to Health from School Flogging.

WE are unfortunatefy too often pained by the disagreeable frequency with whihh irate and inhuman teachers seem to wish to enforce their lessons upon weak and delicate children, mistaking the slowness induced by a natural delicacy of constitution for stupidity. A cry comes to us from a Board School at Chelsea of a little child's hand being severely injured by the cuts from a schoolmistress's cane, but then she was excused from any inhumanity because the little one happened to be "a delicate child, suffering from poorness of blood;" notwithstanding she was obliged to be put under medical treatment.

Another case reported in the newspapers is that of the Rev. Mr. Snowden, of Richmond Grammar School, Yorkshire, who inflicts a brutal flogging upon a small boy for the venal act of "cribbing," and being forced into telling an untruth. Master Thomas Wanless it appears could not accomplish his Latin without the aid of his stepmother; and she at once acknowledged her error, but this did not excuse the boy, for the rev. gentleman saw at once an additional reason why the sins of the parent should be visited on the child; and after having expended his wrath upon him, and turned a deaf ear to the boys cries for mercy, he nevertheless thought himself a merciful man because the "flogging was not administered nearly so hard as he could if he had only tried." As it was, the poor boy after a time went home, "faint, crying, and nervous," nearly frightened to death, and was for some days obliged to be placed under medical treatment. Nevertheless the Head Master is said to be a merciful man, he does not probably practice vivisection upon lower animals, but the law permits him to do so upon human beings. If, however, Head Masters and those paid to teach will persistently ignore their responsibilities and leave teaching to be done at home, they must expect small boys, in difficulties over passages in Cicero, to "crib" and get help from their mothers, but this is no justification for worrying them the next morning into prevarication, flogging them brutally, and degrading them before the whole school. Such proclivities must be checked by bringing schoolmasters and mistresses into courts of law.

A CERTAIN Mr. Pearce, of Andover, was fined last week for the twenty-third time for non-compliance with the Vaccination Act.

AT Grantham, Lincolnshire, last week, a householder named Cammack was fined £5 12s. for sending a domestic servant in a public conveyance whilst suffering from scarlet fever.

OF the 147 candidates for the primary pass in anatomy and physiology at the Royal College of Surgeons, England, during the past few days, more than one-third were referred to their studies for three months.

AT Chesterfield Police Court, on Saturday, Arthur Slater, chemist, of New Whittington, was fined £2 10s. and costs, under the Sale of Food and Drugs Act, for having, when making up medicine from a written prescription, put in an improper quantity of one of the ingredients. He had exceeded by 50 per cent. the quantity prescribed of iodide of potassium.

AT the annual meeting for the suppression of vice, it was stated by the secretary that they had successfully prosecuted three quack doctors for circulating in the London streets hand-bills giving descriptions of and offering medical advice in certain diseases, and that in consequence the nuisance had much abated. Thanks to this society, the practice is much less general; there are, however, plenty offenders to be looked up, whom we hope the society will promptly deal with.

ANOTHER proof, if one were wanted, as to the value of vaccination may be found in the report of the Medical Department of Jamaica. The large public institutions where it was enforced escaped almost entirely the ravages of small-pox, whilst the epidemics amongst the native population who resist vaccination are both frequent and severe. The chief medical officer expresses it as his opinion that the disease would have been extirpated in its early stage but for the obstinate resistance of the coloured population.

MR. GIBSON'S Bill to throw open the Irish County Infirmary surgeoncies to all duly qualified medical men, and to place on the Register the diploma in state medicine of the University of Dublin, has passed. The Irish College of Surgeons, which has hitherto possessed a monopoly of the Infirmary appointments, offered no opposition to the bill, feeling that its provisions were just. It is to be regretted, however, that many similar monopolies continue to exist in England which there are no means of reaching, as they are not maintained under authority of Act of Parliament.

The Medical Defence Association wishes to amend the penal clause of the Medical Act to the following effect:—"Any person whose name is not on the Medical Register who shall take or use the name or title of a physician, doctor of medicine, licentiate in medicine and surgery, bachelor of medicine, master of surgery, bachelor of surgery, surgeon, general practitioner, or apothecary, or any name or title, or addition, implying that he is qualified to practise medicine or surgery, shall, upon a summary conviction for any such offence, pay a sum not exceeding twenty pounds."

◆

MEDICAL OFFICERS OF THE MILITIA.

A Royal Warrant, dated July 12, accompanied by the Secretary of State's instructions thereon, has just been issued, containing important regulations with regard to the pay of medical officers of the Militia Auxiliary Force, and other matters affecting their position. It is intimated that medical officers of the militia who do not, before December 31 next, signify their wish to be placed on a departmental list, shall not be entitled to any of the advantages specified in the present warrant. It is also announced that no further first appointments ef medical officers will be made, after the date of this warrant to the militia, but that militia medical duties shall be thenceforth performed under the orders of the Director-General of the Medical Department of the Army. The names of such medical officers of the militia as shall elect to serve under the direct supervision of the Director-General of the Army Medical Department are to be placed on a departmental list, and the following rules have been established for their future guidance :—

1. Medical officers of the militia who elect to be placed on a departmental list shall only be required to perform army medical duties during the embodiment of their regiment, or during training, or when present during preliminary drill. or recruit drill, or when ordered by competent authority to perform during the non-training period other medical duties connected with the militia, at the place where their regiment is stationed, or where such regiment recruits.

2. Those who held the ranks of surgeon and assistant-surgeon on or before March 1, 1873, shall be commissioned as surgeon-major and surgeon respectively from that date.

3. Those who have been appointed to the rank of assistant-surgeon, or promoted to the rank of surgeon between the 1st March, 1873, and the date of our present warrant, shall be commissioned as surgeon and surgeon-major respectively, from the date of such appointment or promotion.

4. Medical officers of the militia promoted to the rank of surgeon under our present warrant shall, on the completion of twelve years' service from the date of first appointment, be eligible for promotion to the rank of surgeon-major.

5. Surgeons-major and surgeons promoted to those ranks as aforesaid, shall take rank with medical officers of our regular forces as juniors of such ranks in the manner following :—

(a) A surgeon-major shall rank as major, according to the date of his commission; and after twenty years' service as surgeon and surgeon-major he shall rank as lieutenant-colonel, but junior of the latter rank. (b) A surgeon shall rank as lieutenant, according to the date of his commission; and after six years' service, as captain, according to the date of the completion of such service.

6. The rates of pay of the medical officers of the militia during embodiment, preliminary drill, or training, shall be as follow: Surgeon-major, £1 daily; surgeon, 13s. 8d. Their quarters and allowances shall be regulated by their relative rank, as defined in Article 5.

7. Medical officers of the militia who, when performing any of the duties enumerated in Article 1, are in receipt of the full pay and allowances of their rank, shall be liable to be called upon to examine recruits for our regular forces without being entiled to claim any additional pay or remuneration.

8. The allowance to medical officers of the militia for medicines shall not be granted during the training of a militia regiment at a brigade depot, or at a station where there is a military hospital from which medicine can be furnished.

9. The allowances granted to medical officers of the militia for the expenses of necessary medicines and attendance for the non-commissioned officers and men of the permanent staff, and for their wives and families, while the militia regiment is not out for training, shall not be granted when the head-quarters of the regiment are at a brigade depot.

10. Nothing contained in our present warrant shall be held as giving to any medical officer of the militia a claim to any pension or retiring allowance granted to medical officers of our regular forces.

The following are the Secretary of State's instructions on the Warrant:

1. In all cases were battalions of militia are called out for training they will be under the general administration of the principal medical officer of the district. The medical officer of the militia battalion will, under all circumstances, be in immediate charge of his battalion.

2. The medical administration of the brigade depot or other army hospital will, during the training of the militia, remain in the hands of the army medical officer in charge, without reference to seniority of rank.

3. There shall be only one medical officer upon the establishment of a battalion of militia during disembodiment, and supernumaerary officers shall be absorbed as vacancies occur.

4. When a battalion of a militia requires the services of a second medical officer, the Army Medical Department will provide such officer.

5. Militia recruits will be examined by an army medical officer whenever available, at or near the place of enlistment. When not available, the examination will be made by the militia medical officer, or the nearest civil practitioner who is registered for the examination of recruits, preference being given to the former when equally accessible.

6. The medical officers of the militia will also attend the permanent staff of the militia and their families during the non-training period, according to the rules prescribed by existing regulations, when the headquarters are not at the brigade depot; but when the headquarters are at the brigade depot the permanent staff and their families will be attended by the medical officers of the brigade depot.

7. Militia recruits, when trained at a brigade depot or at an army station will be under the medical charge of the army medical officer.

Medical News.

Royal College of Physicians of London.—The following gentlemen were admitted Licentiates :—

Batchelor, Henry Thomas, Worcester, Cape of Gd. Hope.
Bowen, Alfred Longmore, Guy's Hospital.
Buckell, Leonard Martin, Romsey.
Collenette, Frank de Beauchamp, Guernsey.
Fisher, Stephen Henry, London Hospital.
Footner, John Bulkley, Bethlem Hospital.
Gibbes, Cuthbert Chapman, Surbiton.
Hames, George Henry, St Bartholomew's Hospital.
Hancock, John Gatchell, Downshire Hill.
Harvey, William Yeo, Stanhope Street.
Hayes, Francis George, Cathcart Road.
Jackson, Robert Alexander, Notting-hill Square.
Kirtikar, Kanoba Ranchoddas, Euston Square.
Lang, Henry Charles, Berners Street.
Makuna, Manikji Dosabhai, Prince of Wales Road, N.W.
Morshead, Ernest Garstin Anderson, Salcombe Regis.
Perry, Edward Verdon, St. George's Hospital.
Pronger, Charles Ernest, Crawley, Sussex.
Rees, David Valentine, London Hospital.
Ritchie, John Lichtenstein, St. Thomas's Hospital.
Sawtell, Tom Henry, River Street.
Sellon, John William Gore, Budleigh Salterton.
Upton, Alfred, Halton Road.
Vernon, Mark Henry H., St. Bartholomew's Hospital.
Verrall, Thomas Jenner, Dane's Inn.
Walker, George, jun., Cottenham, Wimbledon.
Williams, William Henry, Grafton St., Fitzroy Square.
Woodward, Fredk. Edwd., St. Bartholomew's Hospital.

The following candidates having passed in Medicine and Midwifery, will receive the College Licence on obtaining a qualification in Surgery recognised by this College :—

Eve, Frederic Samuel, Lady Margaret Road.
Lithgow, Thomas George, Kensington Park Road.

Royal College of Surgeons of England.—The following gentlemen passed the Primary Examination in Anatomy and Physiology, at meetings of the Board of Examiners on July 10th, 11th, 12th, 14th, 17th, and 18th :—

H. Evans and A. M. Kavanagh, Dublin; J. Holmes, J. L. Denison, A. N. Young, T. Bushby, P. Canavan, W. T. Clegg, W. A. Beckett, A. Faulkner, and T. W. O. Pugh, Liverpool; A. Harding, King's College; W. H. Wheeler, T. A. Colt, and G. M. Smith, Bristol; F. W. French, W. Muir, W. J.

Pegge, J. Sutcliffe, C. P. Mitchell, and J. H. Thompson, Manchester; H. H. White and W. Bourke, Edinburgh; T. Millar and J. H. Allard, Glasgow; W. H. Cheetham, F. W. Story, W. H. Brown, and G. H. Rowe, Leeds; F. J. Waldo, Cambridge; H. Barron, Liverpool and University College; W. Dales and S. F. Beard, Sheffield; W. L. Lory, R. T. E. Davies, N. S. Witney, and C. B. Hill, University College; F. Spurgin, W. A. Phillips, and F. B. J. Baldwin, Guy's Hospital; R. S. Hawks, C. J. Lathbury, J. E. Nicholson, and J. S. Walker, St. Bartholomew's Hospital; H. W. Thomson, Charing-cross Hospital; W. E. Dixon, Middlesex Hospital; J. S. Fallon and T. G. Munyard, Westminster Hospital; G. J. C. Thompson and A. E. R. Bowen, St. Thomas's Hospital; E. S. Vachell, London Hospital; and T. A. Bertolacci, St. George's Hospital.

Vital Statistics.—From the Registrar-General's return we learn that during last week 5,531 births and 3,290 deaths were registered in London, and twenty-two other large towns of the United Kingdom. The mortality from all causes was at the average rate of 21 deaths annually in every 1000 persons living. The annual death-rate was 19 per 1000 in Edinburgh, 22 in London, 17 in Glasgow, and 17 in Dublin. The annual rates of mortality during the same period in the other large towns were—Norwich 19, Hull 18, Leicester 19, Portsmouth 26, Newcastle-upon-Tyne 22, Birmingham 19, Brighton 20, Leeds 22, Wolverhampton 22, Bradford 21, Sheffield 24, Plymouth 30, Bristol 20, Oldham 29, Manchester 25, Salford 23, Nottingham 15, Sunderland 18, and Liverpool 24. The annual death-rate from the seven principal zymotic diseases averaged 4·8 per 1000 in these towns, and ranged from 0·8 and 1·1 in Newcastle-upon-Tyne and Nottingham, to 5·6 and 7·1 in Portsmouth. Scarlet fever again showed fatal prevalence in Portsmouth. Seven more fatal cases of small-pox were registered in Manchester and Salford in addition to one in the Monsall Hospital. In Liverpool the deaths from small-pox were 20 against 17 and 7 in the two preceding weeks; 3 were unvaccinated cases, and 17 were "not stated" as to vaccination; 2 deaths only occurred from small-pox in London. The deaths from diarrhœa in these towns which in the two previous weeks had been equal to 88 and 188, further rose to 352 last week; the annual death rate from this disease was equal to 3·7 per 1000 in London and to 1·6 in the nineteen provincial towns. No deaths were referred to diarrhœa either in Nottingham or Plymouth, whereas the death rate from this disease was equal to 2·9 in Leeds and Oldham, and to 3·7 in Leicester. In London, the 12 deaths referred to fever were 26 below the corrected weekly average; one was certified as typhus, 10 as enteric or typhoid, and one as simple continued fever.

◆

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the MEDICAL PRESS AND CIRCULAR, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat, after it has passed through the post.

SURGEONS FOR THE ARMY.—In our advertising columns of to-day there appears an official announcement of 50 vacancies for competition in the Army Medical Department, and as there seems to be a disposition on the part of the Government of the day to act more liberally to army surgeons than some of its predecessors we are glad to draw attention to the fact. The salary is now increased to £250, with allowances in addition, and after ten years' service they will be allowed to retire if desired, and be entitled to receive £1000 in lieu of pension. Saturday, August 5th, is the latest date for receiving the names of candidates. Full particulars will be found on reference to our advertisement columns.

THE MEDICAL DEFENCE ASSOCIATION.—Just as we are going to press we are informed that a conviction was obtained at the Wandsworth Police Court on Monday against a chemist of the name of Witherington, residing at 410 Wandsworth Road, S.W., for falsely using the style and title of "Dr." and "Surgeon." The defendant was fined £15 and costs, and in default of distress 21 days' imprisonment.

THE PUBLIC HEALTH (IRELAND) BILL.—The Government announced in the House of Commons yesterday that it would be unable to proceed further with this measure until next session.

THE POLLUTION OF RIVERS BILL will, we fear, be amongst the general "Slaughter of Innocents" Bills this session.

COMMUNICATIONS, Enclosures, &c., have been received from Dr. Pavy, London. Dr. Billing, London. Dr. Pierson, Scarborough. Dr. G. V. Poore, London. Dr. Bernard Kelly, Rotherhithe. Dr. Eberle Easingwold. Mr. Meadows, Hastings. The Secretary of the National Health Society. Mr. Powell, Leeds. Dr. Booth, Chesterfield. Mr. Palmer, St. Thomas's Hospital, Mr. Fowke, British Medical Association. Mr. Kershaw, London Hospital. Dr. Alexander Leadman, Headingley, Leeds. Dr. D. Moore, Walsall. The Secretary of the Charity Voting Reform Association. Prof. Tichborne, Dublin. Dr. Alfred Powell, Newington. Dr. Allschull, London. Dr. Maul, Southampton. Mr. Biddle, Kingsten-on-Thames. Dr. H. Hughes, Bethesda. Mr. Ashenden, Hastings. Dr. Satchell, Kensington. Mr. F. W. Lowndes, Liverpool. Mr. Thomas, Falmouth. Dr. Whiteside Hime, Sheffield. Dr. Tyner, Downpatrick. Dr. Bodkin, Tuam. Dr. Hanrahan, Cappeduff. Dr. Scott, Ballina. Dr. Davys. Dr. Leatham. Dr. Spence, Belfast. Dr. Heeney, Belfast. Dr. Allen, Gorey. Dr. Roche, Fermoy. Dr. Massey, Tubbercurry. Dr. O'Farrell, Dublin. Dr. Rowan, Castlewellon. Dr. Hegarty, Ballinspittle. Dr. Mayne, Ballybrock. Dr. McDermott, Belgarriffe. Dr. Johnston, Westport. Dr. Jalentian, Portarlington. Dr. Scraggs, Clogher. Dr. O'Reilly, Kellishandra. Dr. Maguire, Castleknock. Dr. Mollan, Dublin. Dr. J. Lawrence, Birmingham. Dr. Carey, Taunton. Mr. Blackett, Society for the Relief of Widows of Medical Men. Dr. W. J. Little, London. Mr. Horace Green, Seaford. Dr. Wilson. Vivisectionist. Dr. Langley. Mr. Squire, London. Dr. Martin, Portlaw. Mr. Stuart, &c., &c.

IRISH POOR-LAW INTELLIGENCE.

CORRESPONDENCE.

THE PRESENT WORKING OF THE SANITARY ACTS IN IRELAND.

To the Editor of the "Medical Press and Circular."

Sir,—The Public Health (Ireland) Act has now been in force—I will not say operation—for over a year—a time sufficiently long to enable medical men to judge how it works. Encouraged by the good a former letter which you, Sir, kindly inserted in your journal, has done in this union (it has removed the most objectionable class of wardens—viz., publicans, to their very great indignation), I venture again to trespass on your columns, hoping that this letter may be of some such service as the last. I unhesitatingly affirm that the whole Act is a regular farce. Report after report have I sent in, and, with the exception of some houses being whitewashed after the removal of fever patients, and the little town I live in occasionally getting a dose of whitewash, nothing has been done (oh! I forgot, I beg the guardians' pardon, after a good deal of trouble they mended the handle of the village pump also). Report after report have I sent in as to a supply of water which is badly wanting in a neighbouring village. There is not a drop of water nearer than the river at this time—oily from sheep-washing, and very often in winter yellow with floods. Three hundred children attend the schools, and have no other water than what is collected in half-rotten barrels. Typhoid fever was rife, especially amongst the children, a year ago. In fact, I do not exaggerate when I say that I have no cases now, simply because there are no more to get it. Now, Sir, can it be believed that an unfailing supply of the purest water could be carried into the centre of the village at a cost of ½d. additional to the local rates, and yet the farmers at one side of the river rose in a body against it? I did my best, God knows. If it was a weak work, it was an earnest work. My reports were pooh-poohed at the Board of Guardians. They were referred to the L.·G. B. The L. G. B. sent it to the committee; the committee pooh-poohed it, and sent it back to the Board of Guardians. The workhouse medical officer, I heard, said it was not typhoid fever at all; so the matter dropped.

Now, Sir, the whole thing is in a muddle. The medical officers are generally underpaid. The sanitary sub-officers would be better off if they had not the post at all. My sanitary sub-officer has eleven electoral divisions to look after. He has five small towns and villages to look after, he has five dispensaries to attend, and also the Board. He is supposed to see after the health of the people in a district, the extreme length of which is *nearlg twenty miles*. He was a baker, and had for a village a good connection. He has lost it through reporting nuisances. For his sanitary duties he receives the magnificent salary of £2 10s. per annum! Altogether he receives £27 10s. per annum. How can any man be expected to do his duty as he ought with such a salary? Where can a man fit for the position be got at such a pittance? Loss of connection in his private capacity, shunned by his friends as one who reports, or ought to report, their cesspools and dung-heaps, cold water thrown on his efforts by those who ought to be the first to aid him, left to battle out prosecutions by himself (as happens in this case) against three or four sharp attorneys, who of course all fought against any unprofessional man usurping their right to plead, and for £2 10s.! I need not say what has been the result.

The means authorised by the Act for the prevention of the spread of contagion are totally inadequate. Until persons with fever attended on a red ticket are, if removable, *compelled* to go to hospital, fever will not in the least degree be lessened. I have seen this suggested before by one of the registrars in the Registrar-General's quarterly report. That a pauper should be left at will to spread fever to his family and neighbours is *the most dangerous nuisance of all*, and until this part of the Act is remedied the sanitary laws are, as far as regards the prevention of spread of disease, a dead letter. Again, suppose a pauper anxious to go to hospital, and sent in, say, on Monday, the Board does not meet until Thursday. The sanitary officer sends in his report to the Board, the Board sends its orders to the relieving officer, and in all probability the house is not disinfected until the following Saturday. The circumlocution office is in full swing, and the result generally is that two or three more of the family catch fever before the place is properly purified. Would it not be shorter and better to give the sanitary sub-officers authority to do the thing off-hand, instead of turning the whole matter into a kind of "House that Jack Built"? This is the patient who had the fever, who went into hospital, who infected the house, which the sanitary officer reported to the Board of Guardians, and who gave an order to the sanitary sub-officer, who went out and served it on the occupiers, who refused to carry out the order, and who were reported in a week to the Board, who issued a summons for the occupiers to appear at the Petty Sessions a week after, and when the case was called on there were no appearances, as the rest of the family had gone into hospital, having the fever also, &c.

Another serious obstacle to the proper working of the Act comes—I am sorry to have to say it—from members of the profession, indirectly surely, but still the effect is the same. Dr. Pillbox, of the union, finds it beneficial to depreciate Dr. Scalpel of such a dispensary. He gets private practice by it, and injures the medical character of his opponent. Ah, Sir! these things are so easily done—a pout of the lips, a shake of the head, the use of one term for the disease for another synonymous. Dr. Scalpel sends in a case as fever; it is pneumonia, Dr. Pillbox says, and *vice versa*.

Many of my English readers will think that such things cannot take place. Let them inquire into the relations between union and dispensary medical officers, and they will believe me. I know of a union officer who sent out a case of mild typhoid fever, because the patient had, he said, nothing but *a red tongue.* He never, I believe, uses a thermometer, sent the man staggering out about the road, sent him home to his family, and five or six of the family got it afterwards—nay, sent out a sister of the man as well (he acknowledged hers to be a case of fever), with a temperature of 103°, and a pulse of over 100. I know a medical officer of a union hospital who came behind a dispensary doctor's back, asserted that the girl had simple fever, when the girl's belly was covered with enteric spots—I say covered; the medical man who attended never saw so many. All this grovelling for money, this depreciation of one's medical brethren, to add a few pounds to previous gains. This blasting of young men's characters with a shake of the head tells fearfully against the proper working of the Act. A man with a great name, a large practice, and the union hospital to back and advertise him, thinks it worth his while for the sake of earning a few pounds extra to contradict the diagnosis of a young dispensary doctor. The result is that the young man is not believed. Cases which he pronounces to be fever are left for days sleeping with the rest of the family, and it is only when the whole family are down, and an outcry is raised among the neighbours, that the dispensary doctor is believed. Thus it was that my efforts to get the water so badly wanted failed, because many of my cases of fever were stated not to be fever at all; certainly not typhoid. Why? Listen, physicians,—because there was no diarrhœa!

I say nothing of the opposition offered by the individual guardians and chairmen of Boards to any improvements which cost money. That obstacle is so well known that it would be waste of time to do more than allude to it. I do not wish to enter into the discussion of other parts of the Act which fail of their object. Witness the limits of the powers regarding common lodging-houses to towns of 3,000 inhabitants or upwards. Why, Sir, I know twenty persons to have slept in four beds so closely packed together that the bottom of one touched the head of another in the village I now write in; and, oh! shades of every statesman who ever drew up a law, did anyone ever read anything so ridiculous as the application of 14, 15 V., c. 28, sec. 11-14, to lodging houses in small villages? The lodgers only come at night, are mostly tramps and vagrants, are off by cock-crow in the morning, having communicated to each other, besides the usual compliments in the way of pediculi, itch, scarlet fever, measles, perhaps the seeds of ochlotic fever. How can lodging-house keepers report people who are off next morning perhaps twenty miles? How can a sanitary sub-officer stand sentry to see how many people sleep in the house? To be sure he may make occasional raids. But even if he does, I do not see he has any power in small towns and villages. Is the law-maker so simple as to think the keeper will furnish reports of persons resorting to the house? and that often, even if the keeper had the desire, would have the ability? Why not put villages with less than 3,000 under the Towns Improvements Act? Is fever less contagious in a small village than in a large town? Are there not as bad lodging-houses—nay, worse, in a village than in a large town? Why have not the police power to prevent over-crowding in country lodging-houses? Hoping that I have not trespassed too far on your space,

I remain, Sir,
Your obedient servant,
A DISPENSARY DOCTOR.

* District extends over 10,050 acres, and contains 314,666 persons.

† This district includes City of Dublin and Incurable Hospitals.

LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR THE MONTHS OF MAY AND JUNE, 1876.

MAY.

MAY 10TH.—Peed, Robert Jephson, Wexford, Lic. R. Coll. Surg. Irel., 1867.

12TH.—Geoghegan, Charles Edward, 55 Stephen's Green, Dublin, Lic. R. Coll. Surg. Irel., Lic. 1876 and Lic. Mid. 1876, K. Q. Coll. Phys. Irel.

16th.—Warnock, Hugh, Aughadreenan House, Tintona, co. Tyrone, Lic. R. Coll. Surg. Irel. 1875, Lic. 1876, and Lic. Mid. 1876, K. Q. Coll. Phys. Irel.

17th.—Curtin, Jeremiah O'Brien, Newcastle West, co. Limerick, Lic. R. Coll. Phys. Edin. 1876, Lic. R. Coll. Surg. Edin. 1876.

18th.—Grier, George Robert Macminn, 2 Charleston Terrace, Rathmines, co. Dublin, Lic. R. Coll. Phys. Edin. 1876, Lic. R. Coll. Surg. Edin. 1876.

22nd.—MacPherson, Francis Alexander, 57 Great James Street, Londonderry, Lic. R. Coll. Phys. 1876, Lic. R. Coll. Surg. Edin. 1876.

JUNE.

JUNE 7th.—Searancke, George, Prestatyn, North Wales, Lic. 1876, and Lic. Mid. 1876, K. Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Irel. 1876.

10th.—Nicolls, Arthur George, Ballinalee, Edgeworthstown, co. Longford, Lic. R. Coll. Surg. Irel. 1874, Lic. R. Coll. Phys. Edin. 1876.

10th.—Burke, Andrew Joseph, 3 Eblana Terrace, N. Circular Road, Dublin, Lic. R. Coll. Surg. Irel. 1875.

13th.—Boyle, Thomas, Maghera, co. Derry, Lic. R. Coll. Phys. Edin. 1876, Lic. R. Coll. Surg. Edin. 1876.

14th.—Inglis, James, 61 Broad Street, Aberdeen, N.B., Lic. R. Coll. Phys. Edin. 1876, Lic R. Coll. Surg. Edin. 1876.

15th.—Cosgrave, Ephraim MacDowel, 73 Eccles Street, Dublin, M.B. 1876, and Lic. Surg. 1876, Univ. Dub., Lic. 1876, and Lic. Mid. 1876, R. Coll. Surg. Irel.

15th.—Irvine, George Edward, Poyntz Pass, co. Armagh, Lic. R. Coll. Surg. Irel. 1876.

16th.—Johnston, Arthur Alma, Riversdale Midleton, co. Cork, Lic. 1875, and Lic. Mid. 1875, K. Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Edin. 1876.

26th.—Hoops, Samuel Evans, Kiltubride, Rectory, Carrick-on-Shannon, co. Leitrim, Lic. R. Coll. Surg. Irel. 1874, Lic. 1875, and Lic. Mid. 1875, K. Q. Coll. Phys. Irel.

26th.—O'Connor, Denis Charles, jun., 2 Camden Place, Cork, Lic. R. Coll. Phys. Edin. 1875, Lic. R. Coll. Surg. Edin. 1876.

27th.—MacDonnell, Mark Anthony, Rock Lodge, Newcastle, Galway, M.D. 1876, and M.Ch. 1876, Q. Univ. Irel.

27th.—Connell, Jephson, J., View Ville, Sunday's Well, Cork, M.D. 1876, and M.Ch. 1876, Q. Univ. Irel.

27th.—Williamson, Wm. Cotter, Glenbrook Place Passage West, Cork, M.D. 1876, and M.Ch. 1876, Q. Univ. Irel.

27th.—Murphy, Francis H. S., South Infirmary, Cork, M.D. 1876, and M.Ch. 1876, Q. Univ. Irel.

27th.—Gunning, Robert Cardwell, Enniskillen, co. Tyrone, Lic. R. Coll. Surg. Irel. 1876, Lic. 1876, and Lic. Mid. 1876, K. Q. Coll. Phys. Irel.

28th.—Coyne, Francis Kennedy, Urlingford, co. Kilkenny, Lic. R. Coll. Surg. Irel. 1875, Lic. 1876, and Lic Mid. 1876, K. Q. Coll. Phys. Irel.

30th.—McAfee, William, Ballymoney, co. Antrim, M.D. 1876, and M.Ch. 1876, Q. Univ. Irel.

LONDONDERRY UNION.

REGISTRAR FOR GLENDERMOTT DISPENSARY DISTRICT.

The Clerk said he had received two communications, one from the Registrar-General and the other from the Local Government Board, regarding the vacancy in the situation of registrar of births, marriages, and deaths, for the Glendermott Dispensary District.

It will be remembered that the Derry Board appointed to the situation, but the Registrar-General refused to sanction the appointment on the ground of the candidate's bad hand-writing. Subsequently the Board nominated the dispensary doctor of the district, Dr. Elliot, to the vacancy. The present letter from the Assistant-Registrar-General, dated 10th inst., refused also to sanction Dr. Elliot's appointment, and adding that as fourteen days had elapsed from the occurrence of the vacancy, the appointment had now become vested in the Lord-Lieutenant, under the provisions of the 26th Vic., cap., 11, sec. 25. The communication from the Local Government Board, referring to the proceedings of the Derry Board of Guardians at their meeting of the 8th inst., when they had recommended the appointment of Dr. Elliot as registrar for the Glendermott District, said the minutes of proceedings of that meeting had been forwarded to the Registrar-General, with an accompanying suggestion strongly recommending that Dr. Elliot be chosen to fill the vacancy.

A general conversation ensued the guardians being unanimous in expressing their hope that Dr. Elliot would be appointed.

Mr. Hamilton said he had written to the Local Government Board to say that very great inconvenience arose from not having the offices of vaccinator and registrar combined in the one person. The guardians concurred with Mr. Hamilton,

The Chairman remarking that not to have the two offices vested in the one person would be really punishing the people, who would have so much extra trouble from having to go go to different places for vaccination and registration.

DOCTORS' FEES—DR. BERNARD'S APPLICATION.

An order under the hand and seal of the justices was received for payment of a fee of one guinea to Dr. David J. Browne, on account of examining a lunatic named Margaret Mullen. The examination had been made on the 19th of May, when Dr. Browne was acting as dispensary doctor for Dr. Elliot in the Glendermott Dispensary district. Payment of the fee was ordered.

With reference to the application made to the Board by Dr. Walter Bernard for a fee of five guineas for his attendance in a difficult midwifery case.

The Clerk read a communication which he had received on the subject, containing a recommendation from the Derry Dispensary Committee.

The Committee recommended that Dr. Bernard be paid £2 2s under all the circumstances, Dr. Corbett having certified that a second medical officer was absolutely necessary, but, added the committee, "in future, for the sake of regularity, the order of the Relieving Officer must first be obtained."

The Clerk then read a communication on the matter from Dr. Corbett, medical officer of Derry Dispensary District No. 2, in which he stated that between eight and nine o'clock in the evening of the 28th June, he was sent for by the dispensary nurse to visit a woman in labour residing at the Rock. He hastened to the house and found that Dr. Barnard had arrived there about ten minutes previously. The woman was working in violent convulsions. He remained to give all the assistance he could to Dr. Bernard as he believed her life was in great danger. Had he been there before Dr. Bernard he would at once have applied for additional aid through the Relieving Officer. Dr. Corbett expressed his opinion that, from the extreme urgency of the case, Dr. Bernard, although through some irregularity having been called in, was entitled to some remuneration.

Some of the guardians felt that they had no power to allow Dr. Bernard any fee, from the irregularity in the matter, and others of the Board held the doctor should be allowed some remuneration. They were all willing to do what was fair, but many of them agreed with Mr. Joseph Alexander, that under the circumstances they could not give any fee.

After a short discussion generally,

Alderman Darcus proposed that the Board allow Dr. Bernard the usual fee of two guineas, provided their auditor would pass it.

It was moved, as an amendment, that the matter be referred back to the Derry dispensary committee, and that directions be given to have the lines produced that ordered the nurse-tender and the doctor to the woman.

An amendment was moved that under the circumstances the Board could not allow Dr. Bernard any fee.

The amendment was carried by a majority, after which the matter dropped.

◆

LIMERICK UNION.

THE DEPORTATION OF PAUPERS.

The Local Government Board wrote to say that they had employed solicitors in Warrington, to make the preliminary inquiries into the case of Mary Slattery, and requesting the guardians to give the necessary guarantee for the cost.

It was agreed to give the guarantee and to ask the Local Government Board to have the case of Ellen Slattery inquired into first, and that of the second sister after.

A letter was read from the Local Government Board stating that they had before them the resolution passed at the meeting of the Guardians on the 12th inst. on the subject of the employment of a medical practitioner temporararily in case of necessity to do the duty of either of the visiting medical officers of the Workhouse and in reference there to the Board request that the guardians would be so good as to refer to the 43rd Article of the General regulations to the following effect, "page 250 Irish Med. Directory," prescribing the course to be followed where a union officer is temporarily incapacitated from the discharge of his duty.

Article 43.—If any officer appointed to or holding any Office under this order, be at any time prevented by sickness or accident, or other sufficient reason, for the performance of his duties, the Guardians may appoint a fit person to act as his temporary substitute, and may, subject to the approval of the Commissioners, pay him a reasonable compensation for his services; and every such appointment shall be reported to the Commissioners by the Clerk to the Guardians as soon as the same shall have been made.

The resolution above referred to was at variance with the terms of the 43rd Article, and the proviso to it did not authorise the visiting medical officers to have their duties discharged under certain circumstances by the deputy, and without any special permission, and this ought not to be.

Alderman Myles said the resolution was passed on the last day because it was stated that there was great difficulty in getting a properly qualified person from outside to act as a substitute for any of the visiting physicians who may be absent.

Lord Clarina still thought it would be objectionable to allow the resident medical officer discharge increased duties. The visiting physicians could remain away a month if they liked, and if fever chanced to break out in the house, what a nice condition they would be in.

Chairman—One of the visiting physicians came here the other day and said he could not get a substitute outside because of the manner in which the guardians had treated the doctors.

Lord Clarina—In what respect do they complain?

Chairman—I thought the observation was most uncalled for.

Alderman Myles—The doctors would not come here to be snubbed by the guardians.

Chairman—I don't think they ought to take situations in this house if they are not prepared to hear any reasonable objections which the guardians may have to make as to the manner in which they discharge their duties.

Ald. Myles—The guardians are going rather far with them. They would allow no layman to interfere with them.

Lord Clarina—If the doctors object to the action of the Board they might retire and allow the guardians to appoint others in their place.

It was agreed to adjourn the consideration of the letter from the Local Government Board.

Post-mortem Kindness.—Dr. E. S. Gaillard, in the *American Medical Weekly*, says:

"I knew a physician who went through life with scarcely a word to cheer, encourage, and strengthen him. He was brave enough to endure in silence. He was accomplished, true, and skilful; charitable and kind; but no one ever told him so. He struggled bravely with poverty and adverse circumstances, but there was scarcely one to help him. Troubles thickened about him, but these were not told, and there were none who cared to inquire about them. He struggled always for the right, and to aid in maintaining what was just and true in his profession; but misunderstood, and his actions misinterpreted, he was frequently maligned and seldom supported. He toiled bravely on; a generous husband; a devoted father; a good neighbour; suffering from labour; worn with care; maintaining all the while his family, and adorning his profession; winning gradually a sure foothold and a reliable income. But suddenly he staggered under the load so long carried, and fell. After a brief illness he died. His brethren gathered at his funeral; they profusely decked his bier with the choicest flowers. They recorded before their profession and the public their appreciation of his talent and of his bravery. They praised his energy and devotion. They eulogised his endurance under trial, and his patience in his struggles. There was not a word of aspersion, of contumely, or of blame. Many spoke indignantly of the false charges that had been made against him, and of the unfair treatment that he had received. There was enough said and done then to have gladdened his whole life; to have blessed and made him contented and happy; to have rendered his rugged journey a living sweetness. There was enough of moral sunshine poured over that silent coffin to have made the inmate's life a bright and cloudless day. But it all came too late; the cold ear was now deaf; the once responsive eye for ever closed; the heart that could have been gladdened was still; the hand could no longer feel the friendly grasp and be warmed by it. All was too late. It was the saddest of all manifestations, post-mortem kindness."

THE PHYSIOLOGICAL FUNCTION AND ANATOMY OF THE CRYSTALLINE LENS

A LECTURE DELIVERED TO STUDENTS.

By **Archibald Hamilton Jacob**, M.D. Dublin, F.R.C.S., Surgeon to the Dublin Eye and Ear Infirmary; formerly Ophthalmic and Aural Surgeon to the City of Dublin Hospital.

(Continued from page 67.)

I have in my last communication stated the actual physiology and mechanism of accommodation, so far as it is yet best known, as follows:—

a. The bacillar or Jacob's layer of the retina becomes conscious of the confusion of the image produced by a near object upon the retina when the eye is in a state of rest, and reacts (as is supposed through the ciliary ganglion) upon the brain, the stimulus being reflected through the ciliary nerves to the ciliary muscle.

b. The ciliary muscle contracts. By its circular fibres it is presumed to constrict the venous trunks, thus preventing the return of the blood from the iris and corpus ciliare to the vasa vorticosa of the choroid, and producing erection of the ciliary body. By its longitudinal fibres it draws close together its two attachments, the anterior limit of the choroid, and the posterior margin of the back layer of the cornea.

c. The posterior attachment of the suspensory ligament of the lens at the anterior limit of the choroid being thus drawn forwards, the elastic tension of that ligament is counteracted, and the lens is left free to assume its natural shape.

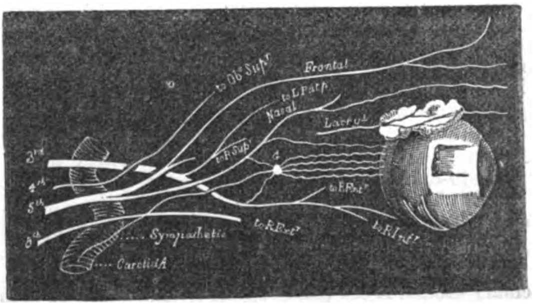
d. Thus relieved of control, the elasticity of the capsule causes the lens to become thicker. The back of the lens being firmly attached to the vitreous scarcely alters at all. The apex of the front advances towards the cornea pushing the iris before it, and the periphery of the lens recedes slightly within the canal of Petit.

The proofs that accommodation is effected by this sequence of physiological acts do not rest alone upon the physical signs demonstrated by Purkinje's experiments which I have already fully described. The theory is supported by other conclusive reasons.

The first of these is afforded by the action of atropia upon the eye with which every one is familar. If a solution of sulphate of atropia, say two grains to the ounce, is applied to the conjunctiva it will be absorbed, and in about twenty minutes will commence to produce a special paralysis of the sphincter fibres of the iris. These fibres derive their motor nerve supply in common with the ciliary muscle from the twig which the third or oculomotor nerve sends to the lenticular ganglion, as is proved by the extreme development of the nerve in those birds of prey in which the ciliary and iris muscles are in their full perfection.

As a comprehension of the nerve supply of the muscles which are involved in the accommodative act is important to an appreciation of the function of the lens, I append an outline illustration of the general nerve supply of the eye.

FIG. 1.



The oculo-motor nerve presided over the contraction of the pupil—the ciliary compression of the lens and the convergence of the eye, which is a necessary part of the accommodative act, and the paresis of the iris produced by the atropia solution which is visible by the enlargement of the pupil is, therefore, accompanied by a similar temporary paralysis of the ciliary muscle which is not visible to the observer, but produces well-defined changes of accommodation sensible to the patient. This change consists in a gradual loss of control over the accommodative function and a gradual lengthening of the distance of accurate vision until, when the process is complete and the pupil fully dilated the eye is accommodated for distant objects, *i.e.*, for parallel rays, and cannot by any effort be brought to focus a near object. The papillary dilatation is, of course, accompanied by dimness of vision, because the rays being admitted through the edges of the lens as well as through the centre, and striking the retina at the sides as well as at the axis of the eyeball, are unequally refracted and unequally discerned by the nerve elements of the retina. But if, by means of a diaphragm with a hole in the centre placed in front of the eye, the rays be confined to their natural path, it will be found that the patient can see distant objects quite distinctly, but is entirely incapable of reading small print or discerning small objects placed close to the eye.

The phenomena thus exhibited prove two facts: Firstly, that the inert relaxed state of the eye is one of accommodation for distance, and that the "thin" form of the crystalline lens is that which it would assume if entirely uninfluenced; secondly, that, inasmuch as this relaxation of the accommodative power is produced by paralysis of the iris and ciliary muscle, those organs must be the active agents in accommodation to near objects.

It may thus be taken as proved beyond reasonable doubt that accommodation is an act of the lens and that that act is consequent upon some influence of the ciliary muscle and iris.

Indeed, Dr. Knapp has decided the former of these statements by showing that when the lens is absent, after cataract removal, not the least trace of accommodative power remains, and he has calculated with apparent accuracy that the change of form of the lens is sufficient to account for the shortening of its focus without conceiving any assistance from other parts of the eye. It being acknowledged, therefore, that the iris and ciliary muscle produce accommodation of their action upon the lens, it remains to be shown in what way they act and which of them is the most important factor in the effect produced. The iris is undoubtedly capable of materially assisting in accommodation, and that it does contract when the eye is brought to bear on near objects any one can see and, in nearsighted persons the effort to accommodate the eye for distance by excluding the scattered rays by closing the lids is a mark of the myopic state. The iris exercises the focussing effect by confining the rays to the centre of the lens the refractive influence of which is much less than that of the periphery, but an observation of Von Græfe's made in the case of a patient whose entire iris had been torn out by accident, and in whom accommodation was, nevertheless, almost perfect proves that it is not an essential or even the principal agent in the focussing of near objects.

As I have said before, it has been stated by Rouget that the annular fibres of the ciliary muscle by contracting compress the irido-choroid venous trunks, and thus forcing all the blood to pass through the ciliary processes, give rise to erection or rigidity of these organs, and he asserts that while thus erect the organs become fitted to transmit to the crystalline lens, in a modified form, the pressure exercised by the ciliary muscle.

This view has been partially adopted in the anatomical section of Mr. Haynes Walton's last edition, in which Mr. Arthur Treherne Norton says—

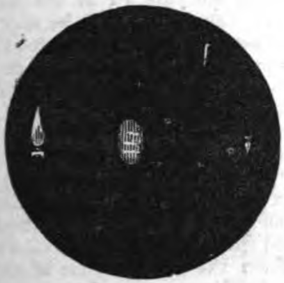
"It is a matter of anatomical deduction that, while the ciliary muscle is the motor power for the effect of accommodation, the ciliary processes are the agents through which the action is accomplished and that the *rapidity* of accommodation is due to the action of the iris. The blood-vessels of the ciliary processes pass through the ciliary muscle near to its apex. Contraction of the muscle, therefore, produces an erectile condition of the processes which in consequence overlap and compress the equator of the crystalline lens. By such compression the lens surfaces are rendered more convex, and the eye is focussed for near vision. Complete erection cannot be momentary, and to obtain rapidity of accommodation the iris comes into play. The plane of the iris is 1-20th of an inch in advance of its attachment. Pupillary narrowing, as is well known, is associated with the accommodation for near vision. When the sphincter pupillæ contracts and narrows the pupil it draws upon the line of attachment of the iris and throws the iris plane back upon the ciliary processes which in turn are pressed against the crystalline lens. If it be said that the iris pressure would rather flatten the processes than compress the lens the answer is that about two-thirds of the fibres of the ciliary muscle are inserted into the connective tissue of the processes, so that when the muscle contracts the processes are drawn towards it and rendered tense upon their contained vessels. No doubt the arrangement of the fibres of the ciliary muscle would enable accommodation to be carried on without the aid of the iris, an explanation of the well-known statement of Græfe to the effect that in one individual instances in which the iris was absent accommodation was not destroyed. That it was imperfect cannot be questioned, for the rapidity of action, a characteristic of the healthy eye, must have been absent."

Whatever truth there may be in this theory which, however ingenious, can hardly claim to be more than a theory, it is evident that not the iris but the ciliary muscle is the essential element in accommodation. This being granted, it is open to discussion how the ciliary muscle acts, and it is right to say, that the theory of the change of curvature of the lens which I have described at so great a length is not universally accepted. In an ably written paper by Dr. Dudgeon, of London, published in January, 1872, it was argued that the interpretation of Purkinje's experiment by Helmholtz and Donders is erroneous, and that exactly similar physical signs of accommodation might be produced by much more feasible means, without alteration of lens curvature.

To this theory Dr. Dudgeon opposes objections both theoretic and practical. He objects to it, in the first place, because he says it involves a supposition that the lens not only changes shape but actually increases in bulk, and he points out that Hensen and Volcker admit this proposition, and endeavour to explain it by a theory that water is actually pumped into the lenticular substance from the canal of Petit. Dr. Dudgeon very justly declines to accept so strained a supposition as this, when, as he thinks, a much simpler explanation of the phenomena is at hand, but I find nothing in the facts stated by Donders, Helmholtz or Cramer which justify the inference that an increase of the bulk of the lens is a part of their hypothesis. Such suppositions is quite unnecessary to their theory, because the assumption of the lens of a more globular form would produce all the refractive effect which is found to occur. Dr. Dudgeon suggests that the supposed receding of the edge of the lens within the canal of Petit does not occur, but both Otto Beeker, who is quoted by Mr. Soelberg Wells (page 501), and Coccius state that they have observed the phenomena in albinotic eyes, and in those in which iridectomy had been performed, and it seems to me that a change of shape observed under the difficulties inseparable from such cases might well be overlooked, even if searched for with the best instrumental aid. Dr. Dudgeon's argument however rests principally upon an observation made by himself:—

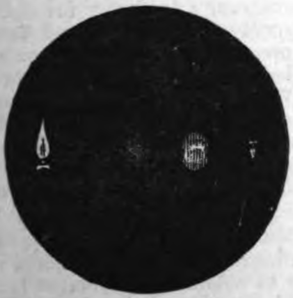
"In order to observe this movement with the greatest accuracy he says, I constructed an apparatus similar in principle to that used by Cramer for the same purpose, but modified in such a manner that I could at will observe the eye from either side, while the candle was placed on the opposite side. In this way I could see the three images of the candle as they were reflected respectively from the cornea, the anterior surface, and the posterior surface of the crystalline. In the figures that follow, representing the appearance of the candle flame in the pupil, the largest bright image is the reflection from the cornea, the large dim image that from the anterior surface of the crystalline, the small bright image that from the posterior surface of the crystalline. When seen through the microscope, all the figures are of course reversed, but I have drawn them in their proper position. When I observed the eye directed to a distant object from the nasal side, the light being on the opposite or external side, I found the dim ill-defined image reflected from the anterior surface of the crystalline occupying a place between the other two bright images reflected respectively from the cornea and posterior surface of the crystalline.

FIG. 2.



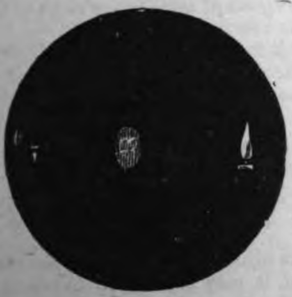
On causing the observed eye to look at a near object on the same line of vision, the dim image moved distinctly towards the large bright image reflected from the cornea (x), and it moved back to its former place as soon as the eye was fixed upon the distant object.

FIG. 3.



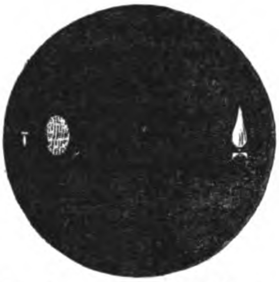
"I now observed the reflection from the external side, the light of the candle impinging on the eye from its nasal side. The three images were again seen nearly in their former positions when the observed eye was directed to the distant object.

FIG. 4.



On again causing the observed eye to look at a near object the dim image now moved through an appreciable space towards the small inverted image reflected by the posterior surface of the crystalline, as shown in the diagram,

FIG. 5.



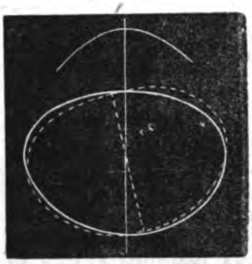
thus proving that the movement of the crystalline was in the same direction as in the former case. Had the anterior surface of the crystalline increased in convexity in adjustment to near vision, it is obvious that in both cases the image of the candle reflected from its surface would have appeared to move towards the apex of the convexity, to wit, the centre of the pupil, but, on the contrary, in both instances it moved towards the external edge of the pupil, showing that the change in the crystalline was merely a change in the aspect or slope of its anterior surface, and that this change consisted in a slight movement of rotation from without inwards.

"The figures given by Cramer distinctly agree with what I myself observed in looking at the eye from the nasal side. But the figures given by Donders, which I here reproduce, show conclusively that the motion of the crystalline is as I have stated it to be."

This is undoubtedly a very important observation, and one which the theory of increase of curvature of the lens does not sufficiently explain.

Dr. Dudgeon's theory is that the lens does not alter in curvature at all, but that it is rotated upon its vertical axis when accommodated to near vision, and that thus a greater thickness of lens is interposed in the optical axis and a corresponding increase of refraction produced. The following is the figure which begins the dotted line representing the supposed position of the lens in near vision :—

FIG. 6.



The peculiar ellipsoidal shape of the crystalline, he says, allows this tilting movement to take place with much less disturbance of parts than would occur were its surfaces spherical, and the increased refractive power is greater than in the case of spherical surfaces, owing to the greater convexity of the ellipsoid towards its circumference. This property of that geometrical figure will ensure a shortening of its focus by its mere inclination independently of an increased thickness of the refractive medium through which the rays of light have to pass (though this, too, occurs in a slight degree), which is the sole means by which the shortening of the focus is effected in the case of a lens with spherical surfaces."

Two obvious objections to Dr. Dudgeon's theory present themselves. Firstly, that rotation of the lens involves considerable aberration, and should be supposed to be attended with dimming of the sight. Secondly, that we know of no mechanism capable of producing such an effect on the position of the lens in the eye. He disposes of the first of these objections by conceiving that this aberration, like all other optical faults in the eye, is corrected by the closure of the pupil, and he is accurately correct in his appreciation of the effect of an optical diaphragm, for I believe that a reduction in the papillary aperture is quite capable of correcting much more powerful aberrative influences than that supposed by Dr. Dudgeon. In January, 1868, I communicated to the Surgical Society of Ireland a case (published in the MEDICAL PRESS of that date) in which an artificial iris had restored almost perfect vision to a man whose iris and lens had been completely torn away, and it is, therefore, conceivable that a slight degree of aberration might be enterely remedied by the concurrent contraction of the pupil which is acknowledged to take place.

It is the weak point of Dr. Dudgeon's theory that he is unable to form even a reasonable theory of the means by which the rotation is effected.

"With regard to the muscular power by which the motion of the crystalline lens I have described is produced," he says, "I am unable to say anything very definite. If I might be allowed to hazard an opinion, I would say that the action of the external fibres of the ciliary muscle on the zonula Zinnii might be competent to produce this tilting operation."

The firm connection between the lens and vitreous would also seem to render impossible any change of position such as he supposes.

His views certainly claim attention and consideration from the care and industry with which he has dealt with the subject, and if there are some difficulties in his theory which yet wait for solution, it seems, nevertheless, almost as reasonable a supposition as any which have yet been put forward.

THE CHEMISTRY OF EVERY-DAY FOOD.

By H. C. BARTLETT, Ph.D., F.C.S.

IN dealing with the subject of the chemistry of every-day food it is necessary to explain that, however interesting in itself, the pure chemistry of food affords but small means of understanding how food is transformed into the bodily tissues, unless a knowledge of human physiology is presupposed.

Unless, indeed, the physiology of the human body is made popular, at least to the extent of explaining the intimate relationship of both the elements and proximate principles which compose alike the tissues and juices of the body, and also form the whole of the constituents of mixed food. The more important principles involved must be studied under the dual aspect of nutriment, assimilative or formative matter, and the formed substances proceeding through the various changes of tissue towards their ultimate elimination or decomposition.

Analysis shows perpetual change to be taking place at all times during the growth of food substance, and also in the bodily fabric after the nourishment has become assimilated; for this latter reason we are unable to state with definite accuracy how much soluble albuminoid matter, how much of the harder fibrinous portion of food, what quantity of hydrate of carbon, or fatty matter are required to make good the waste that has occurred during any stated period.

We have to take into account the effects of exertion, whether occasioned by gentle exercise, hard work, or over-exertion. To some extent we are also dependent upon the election of appetite predisposing the individual to accept with greater or less avidity foods of different flavours and textures.

The idiosyncrasies of different individuals must be consulted, the condition of health from time to time being an important factor in any estimation as to the relative value of different kinds of food during any experimental period. Climatic influence and even mental temperament must be taken into account before any just realisation of what is required to sustain the body in the highest type of health can be approximately ascertained.

If it is impossible to deal with individual requirements with any degree of certainty, the system of average which can be so admirably brought into play in feeding considerable numbers is well illustrated by the dietaries of the army and navy, of our prisons, workhouses, hospitals, and schools. We have fortunately tabulated for us various scales of dietaries, which have been found to range from those most economical, which have been proved to be somewhat less than perfectly efficient, such as the old scale of the Perth Gaol, to the somewhat superfluous apportionment of food still, with perfect justice, supplied to the Royal Navy.

If, on the one hand, a general decrease of weight in the Perth prisoners proves the amount of labour there exacted to have been more than the dietary would sustain without loss of muscular substance, so on the other, notwithstanding the hard work and pure air of the naval service, the appetites of our seamen appear to be very generally satisfied with the plentiful though coarse food accorded them. This, in some instances, may occasion a certain amount of waste, but I cannot for my own part esteem a superabundance of food to be altogether thrown away in the endeavour to secure plenty, or at least an assurance that none shall be actually under-fed.

For the purpose of arriving at the most reliable results derivable from the different systems of dietary adopted in the services and institutions above named, I, some time back, addressed particular inquiries to the medical officers in charge. From the general tenor of their remarks, as well as from the Government reports which were kindly collated and forwarded to me, I have little doubt but that these scales will afford a most efficient and economical general scheme of diet.

It is well to bear in mind, however, that the most practical and advantageous use of consulting a comprehensive tabular system of diet is to avoid the common dependence on haphazard selection. The ordinary every-day food of the general community is almost invariably purchased, cooked, and served without the slightest knowledge of the quantities or proportions of any of the proximate principles or ultimate elements required for the sustenance of the consumers. With a total of food substance sometimes superfluous, an inadequate constituent of fat or digestible albuminous matter may leave the meal little better than a mechanical appeaser of hunger, altogether incompetent to repair muscular or nervous waste or recruit exhausted energy.

Each individual may choose for his own personal requirements or tastes from a large number of various articles of food so as to obtain relief from undue monotony of flavour or texture, but the choice should be made so as to keep the proportions of the main constituent principles within certain relative limits, although these proportions do not by any means demand a hard and fast line to be laid down.

It may be stated that if the best theoretical economy of food be desired, the relative proportions of the nitrogenous substances to the fats and carbo-hydrates must be maintained, or starvation of some one or more of the body tissues will inevitably ensue.

To the flesh-forming nourishment derivable from the albuminous or nitrogenous substances and the proportion of fat, on the one hand, and starch, gum, and sugar on the other, may be centesimally represented as follows :—

Albuminates	22
Fat	13
Carbo-hydrates	65
	100

Or, taking the ultimate elements of the standard diet for an adult man, it may be roughly calculated as requiring 300 grains of nitrogen, 4,500 grains of carbon, and 450 grains of mineral matter; and in whatever way the diet may be made up of various different compounds, less than such an average in this proportion may be deemed insufficient to support hard work.

If the science of dietetics were habitually carried beyond the mere supervision of the medical profession during periods of ill health, so that a proper diet generally suitable must be modified to individual necessities, many diseases of mal-nutrition would probably be averted.

It may be, perhaps, too much to expect that popular education would include a sufficient insight into the principles involved to enable everyone to form such an estimate for himself. To accomplish the very desirable end of apportioning food so that it is neither wasted nor provided too sparingly in any of its essential components, we must first look forward hopefully towards the recognition of the importance of the science of dietetics, especially by those whose opportunities would enable them to compare the results of various dietaries, in studying the immediate and continued effects upon health of the different kinds of food.

A COURSE OF PAPERS ON THERAPEUTICS: INCLUDING THE PHYSIOLOGICAL ACTION OF MEDICINES.

By W. Handsel Griffiths.

(Continued from page 595 in last Volume.)

ACIDUM HYDROCHLORICUM.

Hydrochloric acid exerts a feebler caustic action than nitric or sulphuric acids; it leaves a white stain on the skin which afterwards sloughs.

In tinia, itch, and psoriasis Pleuck suggests the use of ointments or lotions containing hydrochloric acid, and in frostbite also it has proved a useful application; warts and small fungous growths may be removed by it. In hospital gangrene, scrofulous ulcers, &c., its topical use has been attended with beneficial results. By Erichsen the internal administration of muriatic acid in chronic eczema has been found successful.

Given internally in small doses hydrochloric acid causes an agreeable warmth in the epigastrium, and combined with bitters may be given as a stomachic tonic: it should not be forgotten, however, that it tends to relax the bowels rather than to exert a stringent effect.

In the diluted form hydrochloric acid agrees better with the stomach than either dilute nitric or sulphuric acids. When given internally in a concentrated form it combines with the albumen and tissues of the stomach, and acts as a caustic irritant. On the supposition that hydrochloric acid is an ingredient of the gastric juice, it has been recommended in certain cases of indigestion, and has been found especially serviceable in those resulting from excesses of eating or drinking. In the writer's opinion, hydrochloric acid is far superior in the treatment of indigestion to all other acids, not excepting lactic, which has received a large mead of praise. The addition of pepsin aids the digestive action of the acids. It should never be forgotten that acids should be given *after* meals; if given before they will hinder rather than aid the digestive process. Alkalies, on the other hand, should be administered before meals, if given with a view of assisting digestion. The action of alkalies and of acids on secreting glands affords an explanation of these facts, for acids check the production of acid secretions from glands, while they promote the flow of alkaline secretions, and the reverse is the case with alkalies.

In pyrosis, characterised by acid eructations, hydrochloric acid given before meals will prove an effectual remedy, whereas in pyrosis with alkaline eructations the administration of an acid after meals will effect a cure. Ringer suggests that in pyrosis with alkaline eructations the administration of an alkali shortly before food would be productive of good, but he states that he has no experience of the use of alkalies in such cases. In one remarkable case of this kind the author has obtained remarkably successful results with the alkaline treatment. It is necessary to caution practitioners against the too long continued administration of acids in these affections of the stomach.

On the ground that hydrochloric acid forms an important constitutent of the gastric juice, and that it increases the efficacy of the assimilative process, and thus prevents the formation of lithic acid in excess, Dr. James F. Duncan recommended it in chronic forms of gout. *(a)* He gives a mixture of dilute hydrochloric acid, two drachms; compound tincture of cardamems, two drachms; bitter infusion, seven and a-half ounces; of this an ounce is given every three hours.

Acids lower the rapidity of the pulse in fever, owing to their diminishing the thirst, and thus lessening the restlessness. To relieve the thirst in fevers, Graves, of Dublin, recommended the administration of hydrochloric acid in infusion of cascarilla; it may also be given in barley water. In typhus and typhoid fevers hydrochloric acid has been recommended as a remedy by many authorities, and it is generally acknowledged that its efficacy in those cases is enhanced by combining it with quassia or cinchona, &c. It is supposed to act by neutralizing the excess of alkali in the blood. Huss states that in an epidemic of typhus fever in Stockholm, in 1841-2, hydrochloric acid was almost entirely relied upon, and especially in cases characterized by cerebral symptoms; bronchial and pulmonary congestions were the only complications which were regarded as contraindicating the administration of this remedy. Dr. McSherry speaks highly of the use of hydrochloric acid in scarlatina, in doses of from one to three drops well diluted.

Hydrochloric acid has been given as a tonic in phthisis, and Dr. Cotton especially recommends it for the relief of the dyspepsia and debility of this disease.

In diphtheria Bretonneau used a mixture of one part of the acid and two of honey as a topical application; if the pure acid be used for this purpose care should be taken to apply it only to the parts actually covered by the exudation. In cancrum oris and phagedenic ulcerations, &c., hydrochloric acid has also been applied, and in the different forms of stomatitis it may be advantageously used as a gargle or in the form of spray—a drachm or two of the acid being mixed with twelve ounces of water sweetened with honey. Panck recommends hydrochloric acid in hooping-cough in doses of ten minims several times daily.

In small doses hydrochloric acid promotes the flow of urine. In the phosphatic forms of stone and gravel, and in lithiasis it is extensively given. Prout prefers hydrochloric acid to all others in the treatment of oxalic acid diathesis; in this and in cystic oxide diathesis its use should be continued until lithate of ammonia or lithic acid begins to appear in the urine when it should be stopped.

Hydrochloric acid has been used in the treatment of diabetes in large doses; it causes a peculiar cerebral excitement, giving rise to a species of intoxication.

Piroleau was the first to call attention to the antisyphilitic virtues of hydrochloric acid, and among other authorities who have written favourably of it as a remedy in syphilis are Zeller, Rust, and Pearson. Rust considers that abstinence is an essential element of success in this treatment; he found that it invariably failed when a full diet was allowed. The formula used in the Vienna hospital was a drachm of the acid to two pints of barley water daily. In gangrenous ulceration of the genitals Van Swieten employed an application of the strong acid diluted with six parts of water with great success.

In poisoning by hydrochloric acid the most appropriate antidotes are magnesia and carbonate of soda; emollient drinks should also be freely administered. Chalk is objectionable as an antidote on account of the deleterious properties of the chloride of calcium which it forms with the acid.

(a) *Dub. Quart. Journ. of Medical Science.* May, 1865.

ROYAL SOCIETY.

RESEARCHES ILLUSTRATIVE OF THE PHYSICO-CHEMICAL THEORY OF FERMENTATION, AND OF THE CONDITIONS FAVOURING ARCHEBIOSIS IN PREVIOUSLY BOILED FLUIDS.

BY H. CHARLTON BASTIAN, M.A., M.D., F.R.S.,
Professor of Pathological Anatomy in University College, London, and Physician to University College Hospital.

THE author first calls attention to the fact that no previous investigator has professed to have seen well-marked fermentation set up in urine that had been boiled for a few minutes, if it has thereafter been guarded from contamination. The previous invariable barrenness of this fluid after boiling has been ascribed by germ-theorists to the fact that any organisms or germs of organisms which it may have contained were killed by raising it to the temperature of 212 degs. F. (100 degs. C.).

In executing some of the experiments with urine described in this communication, two chemical agents have been brought into operation under novel conditions, and an ordinary physical influence has been employed to an entirely new extent. In several respects, therefore, these new experiments differ much, as regards the conditions made use of, from those hitherto devised for throwing light upon the much-vexed question as to the possible origin of Fermentations independently of living organisms or germs, and as to the present occurrence or non-occurrence of archebiosis.

The chemical agents employed under new conditions in these experiments were *liquor potassæ* and *oxygen*—both of them being well known as stimulants, if not as promoters, of many fermentative processes.

It has been recognised by several investigators of late years that neutral or slightly alkaline organic fluids are rather more prone to undergo fermentation than slightly acid fluids. This fact may be easily demonstrated. As the author pointed out in 1870, if two portions of an acid infusion are exposed side by side at a temperature of 77 degs. F. (25 degs. C.) fermentation may be made to appear earlier and to make more rapid progress in either of them by the simple addition of a few drops of liquor potassæ; on the other hand, if a neutral infusion be taken and similarly divided into two portions placed under the same conditions, fermentation may be retarded, or rendered slower in either of them at will, by the simple addition to it of a few drops of acetic or some other acid.

A neutral or faintly alkaline organic solution can in this way be demonstrated to possess a higher degree of fermentability than an otherwise similar acid organic solution. It seems, therefore, obvious that the changes capable of taking place in *boiled* acid and neutral solutions respectively should also vary considerably. Numerous experiments by different observers have demonstrated the correctness of this inference. ‘ Boiled acid infusions guarded from contamination mostly remain pure and barren if kept at temperatures below 77 deg. F. (25 deg. C.), though other infusions similarly treated and similar in themselves, except that they have been rendered neutral by an alkali, will oftentimes become corrupt and swarm with organisms. The latter result follows still more frequently with neutral infusions when they are exposed to a higher generating temperature in the warm-air chamber; and under this strong stimulus a small number of boiled acid fluids will also ferment.

On the other hand, the influence of oxygen in promoting fermentation has been fully appreciated since the early part of the present century. Formerly an influence was assigned to it as an initiator of fermentation as all-important as some chemists assign to living germs at the present day. But this was a very exaggerated view. In some fluids, as the author has shown, fermentation may be initiated just as freely, or even rather more so, in closed vessels from which the air has been expelled by boiling, as in others in which atmospheric air, and consequently oxygen, is present. The explanation of this fact is probably to be found in the supposition that, in starting the fermentation of these fluids, diminution of pressure may be of as much, or even of more importance than contact with free oxygen. In respect to other organic fluids, however, the influence of oxygen seems decidedly more potent as a co-initiator of fermentation than that diminution of pressure which is brought about by hermetically sealing the vessel before the fluid within has ceased to boil. Urine will be found to be an example of this latter class of fluids.

The physical influence which has been employed in unusual intensity in the present researches is *heat*.

Previous experimenters have never designedly had recourse to a generating or developing temperature above 100 deg. F. (38 deg. C.). The heat employed has frequently been below 77 deg. F. (25 deg. C.), though a temperature between this and 95 deg. F. (35 deg. C.) has been regarded both by chemists and biologists as most favourable to the occurrence and progress of fermentative changes generally.

Early in the month of August, 1875, the author ascertained the fact that some boiled fluids which remained barren when kept at a temperature of 77 deg.—86 deg. F. (25—30 deg. C.) would rapidly become turbid and swarm with organisms if maintained at a temperature of 115 deg. F. (46 deg. C.). More recently he has discovered the surprising fact that a generating temperature as high as 122 deg. F. (50 deg. C.) may be had recourse to with advantage in dealing with some fermentable solutions. Fluids which would otherwise have remained barren and free from all signs of fermentation have, under the influence of this high temperature, rapidly become turbid and corrupt. This discovery is regarded as of great importance in reference to the questions now under discussion, and it is one which was quite unexpected. The author had previously shared in the generally received opinion that temperatures above 100 deg. F. (38 deg. C.) were likely to impede rather than promote fermentation.

In maintaining the experimental fluids at the high temperature above named the vessels containing them were placed in the hot-air chamber of an incubator, such as physiologists employ, to which one of the very ingenious gas-regulators of Mr. F. S. Page had been fitted (see *Journal of the Chemical Society*, January, 1876). In this way the fluids may be kept at a known and practically constant temperature for an indefinite time.

Liquor Potassæ as a Promoter of Fermentation in Boiled Urine.

In the autumn of 1875 the author instituted some experiments to ascertain whether the fermentability of boiled urine, like that of many other fluids, could be increased by previously mixing with it a quantity of liquor potassæ sufficient for its neutralization.

The experiments answered this question in the affirmative. It was found that urine to which the above-named amount of liquor potassæ had been added, would constantly ferment and swarm with organisms within a few days after it had been boiled; though some of the same stock of urine in the acid state (that is, without the addition of any alkali) would, when similarly treated in other respects, remain barren. The fact of the production of an increased fermentability in boiled urine by previous neutralization was thus established.

Further experiments were then instituted to throw light upon the cause of such increased fermentability. It was desirable to ascertain whether (1) it was due to survival of germs in the boiled neutralised fluid, or (2) to the chemical influence of potash in initiating or helping to initiate the molecular changes leading to fermentation in a fluid devoid of germs or other living matter.

The mode of testing the relative validity of these rival interpretations seemed easy. It was only necessary to ascertain what the effect would be of adding boiled liquor potassæ, in proper quantity, after the acid urine had been rendered barren by boiling it instead of adding it previous to the process of ebullition. If fermentation occurred in the fluid thus neutralised without extraneous contamination, the first interpretation would obviously be negatived.

This crucial experiment was at first tried with flasks plugged with cotton wool, the plug in each of them being penetrated by a closed glass tube containing the measured amount of liquor potassæ. The tubes having been drawn out to a capillary portion at the lower end, and bent at an obtuse angle, they could be easily broken by slight downward pressure against the bottom of the flask whenever it was desired to mix the liquor potassæ with the boiled urine. This apparatus was very similar to that first made use of by Dr. William Roberts in some experiments with hay infusion (Phil. Trans. vol. clxiv. p. 474), in which he obtained opposite results from those now about to be recorded with urine. The latter fluid is, however, for several reasons more suitable than hay infusion for trying such experiments.

Several trials made with urine in this apparatus showed that its fermentability was just as much increased by adding boiled liquor potassæ after the urine had been boiled in the acid state, as by adding the alkali previous to the process of ebullition. Such a result was therefore quite opposed to the first interpretation as to the cause of the increased fermentability of neutralised urine.

The definite overthrow or establishment of this interpretation was so important that it seemed desirable to try such experiments again by some more rigid and certain method. The author therefore devised a new mode of experimentation in which sealed retorts replaced the flasks plugged with cotton wool, and in which the contents of the enclosed liquor potassæ tubes could be more effectually heated.

It was first of all ascertained that accurately-neutralised urine boiled in a retort and sealed whilst boiling, would ferment in a day or two if kept at a temperature of 122 deg. F. (*a*)

This fact having been established, other retorts were charged with a measured amount of urine, and also with a small glass tube containing liquor potassæ in quantity almost sufficient to neutralise the urine employed. (*b*) The glass tubes containing the liquor potassæ had been drawn out at one end, sealed, and then immersed in boiling water for different periods before introducing them into the retorts. After each retort had been charged with urine and a liquor potassæ tube, its neck was drawn out to a capillary point, the urine was boiled, and the retort was hermetically sealed before ebullition had ceased. Thus closed, the vessel was at once immersed with its neck downwards in a can of boiling water for from four to fifteen minutes, so as to expose it and its contents for an additional period to a temperature of 212 deg. F. (100 deg. C.).

The urine was thus boiled in its unaltered acid state and sterilised. After the retorts had cooled the liquor potassæ was liberated from its tube in all but one of the batch, which was kept as a control experiment. The liberation was easily effected. It was only necessary to give the retort a sudden shake so as to drive the capillary neck of the enclosed tube against its side. The tube was thus broken and immediately (owing to the comparative vacuum within the retort) the liquor potassæ was sucked out and mixed with the fluid which it was destined to neutralise.

The result of these experiments was similar to those executed with the plugged flasks and liquor potassæ tubes. The boiled caustic potash added afterwards within the sealed retorts caused the previously barren fluids to ferment and swarm with *Bacteria*. The fluid in the control experiment remained pure, though after several days, or longer, it also could be made to ferment by breaking the liquor-potassæ tube, and replaced the retort in the warm chamber.

Effects of liberating Oxygen by Electrolysis within the Closed Retorts.

A few other experiments were made with retorts to which platinum electrodes had been fitted. These contained, as before, measured amounts of urine, together with liquor potassæ tubes. All the preliminary stages were similar to those of the experiments above recorded; but just before breaking the liquor potassæ tubes in these further experiments, oxygen and hydrogen were liberated from the boiled urine by electrolysis.

The result in the few experiments made was very remarkable. Under the combined influence of liquor potassæ, oxygen and the high temperature of 122 deg. F. (50 deg. C.), the sterilised urine fermented and swarmed with *Bacteria* within the closed retorts in from 7—12 hours—that is, in a much shorter time than would suffice for the occurrence of similar changes in unboiled urine freely exposed to the air.

Behaviour of some specimens of unaltered Acid Urine under the influence of the High Generating Temperature of 122 deg. F. (50 deg. C.)

In the course of the previous experiments it was found that occasionally a specimen of boiled urine would ferment at a temperature of 122 deg. F. without the addition of liquor potassæ. This was afterwards ascertained to occur invariably (with the urine experimented upon) when the acidity of the fluid was not higher than would be represented by six minims of liquor potassæ to the ounce (or about 1½ per cent.). Urines slightly more acid than this sometimes did and sometimes did not ferment without liquor potassæ; but when the acidity exceeded what would be equivalent to two per cent. of liquor potassæ, the fluid did not ferment under the influence of the high generating temperature alone. Urines of all degrees of acidity, however, were found to ferment under the combined influence of heat and liquor potassæ added afterwards, in the manner already detailed. (*a*)

It was further ascertained that the acidity of some specimens of urine was lessened during the process of ebullition (owing to the deposition of acid phosphates); and such urines boiled for six minutes were found to ferment in a much shorter time than when they were only boiled for three minutes. The prolongation to this extent of the germ-destroying temperature actually hastened the subsequent process of fermentation.

Interpretation of Results.

The generally received belief that all *Bacteria* and their germs are killed by exposing them even for a minute or two to the temperature of 212 deg. F. (100 deg. C.) has of late been strongly reinforced by Prof. Tyndall. The fact, therefore, of the fermentation of some specimens of boiled acid urine, with the appearance of swarms of *Bacteria*, under the influence of the high generating temperature of 122 deg. F. (50 deg. C.), is inexplicable except upon the supposition that fermentation has in these instances been initiated without the aid of living germs, and that the organisms first appearing in such fluids have been evolved therein.

If the author's further position (Proceedings of Royal Society, Nos. 143 and 145, 1873), that *Bacteria* and their germs are killed in fluids whether acid or alkaline at a temperature of 158 deg. F. (70 deg. C.), is correct, then the occurrence of fermentation in the previously neutralised boiled urine would similarly disprove the exclusive germ-theory of fermentation and establish the occurrence of Archebiosis.

Any difficulty which might have been felt by others in accepting the above interpretation of the results of these latter experiments—in face of the view held by M. Pasteur that some *Bacteria* germs are able in neutral fluids to survive an exposure to a heat of 212 deg. F. (100 deg. C.)—has been fairly met and nullified by the experiments (devised for the purpose), in which the urine was boiled in the acid state and subsequently fertilised by the addition of boiled liquor potassæ.

If we look at these latter experiments from an independent point of view, it will be found that this fertilisation of a previously barren fluid by boiled liquor potassæ must be explained by one or other of three hypotheses :—

1st *Hypothesis. The boiled liquor potassæ may act as a fertilising agent because it contains living germs.*

However improbable this hypothesis may seem on the face of it, it has been actually disproved by many of the experiments recorded in this memoir, These experiments show that boiled liquor potassæ will only act as a fertilising agent when it is added in certain proportions. If it acted as a mere germ-containing medium, a single drop of it would suffice to infect many ounces, a gallon, or more of the sterilised fluid. This, however, is never the case; it only fertilises the barren urine when it is added in a proportion dependent upon the precise acidity and quantity of the fluid with which experiment is being made.

2nd *Hypothesis. The fertilising agent may act by reviving germs hitherto presumed to have been killed in the boiled acid urine.*

The acceptance of this hypothesis would involve a general recantation of the previously received conclusion that *Bacteria* and their germs are killed by boiling them in acid fluids. But such a recantation would be scarcely justifiable or acceptable unless based upon good independent evidence.

The possibility, however, of accepting this second hypothesis is still further closed by the results of experiments in which a slight excess of liquor potassæ was added to the boiled urine. Such fluids invariably remained barren. Yet it can be easily shown that the mere development and growth of *Bacteria*-germs may take place both quickly and freely in boiled urine containing a very large excess of liquor potassæ. (*b*)

(*a*) Though the boiled urine will ferment in retorts from which the air has been expelled by boiling, it will undergo this change more quickly if it is in the presence of purified or sterilised air. In the experiments now about to be described, however, it was much more convenient to use airless retorts.

(*b*) As a slight excess in the amount of liquor potassæ has been proved to have a most restrictive influence when dealing with urine, it was found safer in these experiments not to provide liquor potassæ sufficient for full neutralisation. Many details on this subject are given in the memoir itself.

(*a*) In the urine of highest acidity with which experiment has been made, twenty minims of liquor potassæ to the fluid ounce (about 4 per cent.) was required for neutralisation.

(*b*) A mixture of one part of liquor potassæ to seven of boiled urine poured into a bottle which has been washed with ordinary tap-water will, within forty-eight hours, swarm with *Bacteria* if it is kept at a temperature of 122 deg. F.

It would seem that this agent mixed with boiled urine in quantity slightly more than is needed for neutralisation, prevents the *origination* of living matter therein, although even when in considerable excess the same agent affords no obstacle to the development, growth, and multiplication of germs purposely added thereto.

In the face of these facts it would seem impossible to accept that second hypothesis, even if it had not been independently negatived by the great mass of evidence—lately reinforced by the experiments of Prof. Tyndall—to the effect that *Bacteria* and their germs are really killed in fluids raised for a few minutes to the boiling-point (212 deg. F.).

3rd Hypothesis. The fertilising agent acts by helping to initiate chemical changes of a fermentative character in a fluid devoid of living organisms or living germs.

If the cause of the fermentation of the fluids in question does not exist in the form of living organisms or germs either in the fertilising agent itself or in the medium fertilised, then it must be found in some chemical reactions set up between the boiled liquor potassæ and the boiled urine.

Clinical Records.

METROPOLITAN FREE HOSPITAL.

Case.—*Poisoning by Medicinal Doses of Iodide of Potassium.*

A man, aged 36, entered the wards of the hospital in May, 1867, under Dr. Charles Drysdale's care with right hemiplegia, which had evidently been caused by an embolism, as there were abnormal sounds of the valves of the heart. As some symptoms in addition pointed to dilatation of the ascending arch of the aorta he had, on three several occasions prescribed ten grain doses of the iodide of potassium thrice daily in water. On the first two occasions the effect was to produce a crop of acne-like pustules on the face. The last trial, which lasted three days, brought forth an alarming-looking eruption on the backs of the hands as well as on the face and chest. Blebs were formed containing a bloody fluid, which lasted without dessicating for some weeks.

Remarks.—A case in the wards under the care of a late colleague of Dr. Drysdale's presented a most severe example of the same rare effects of the iodide of potassium.

◆

ST. MARY'S HOSPITAL.

Death from Crude Carbolic Acid taken by Mistake.

Reported by Mr. Giles.

A. H., æt. 10, was admitted into the hospital with the following history: About one hour previous she, being thirsty, had swallowed a part of the contents of a ginger-beer bottle, thinking it contained ginger-beer. The bottle contained a quantity of strong crude carbolic acid which had been obtained for the purpose of destroying vermin, and she swallowed what proved to be a fatal dose before she discovered her mistake. The patient ran shrieking to a neighbour complaining of burning in the throat and severe epigastric pain; she grew rapidly worse and soon became insensible.

On admission the patient was found to be in a state of collapse; the conjunctiva were insensitive, and the pupils fixed and insensible to light; the surface was cold and clammy; the respiration slow, laboured, and stertorous, and the pulse weak and infrequent.

The house-surgeon, Dr. Wise, passed the stomach-pump, and having thrown in a quantity of water pumped out a blackish fluid smelling strongly of carbolic acid, after which some oil was injected.

The patient, however, continued to sink, and it was determined to try the intra-venous injection of ammonia. This was done but without any effect, and she died two hours after her admission to the hospital.

Post-mortem Examination.—Body well formed and nourished, and wonderfully free from decomposition. On opening the cavities a strong smell of carbolic acid could be perceived; the pleuræ, pericardium, and peritoneum, each contained a small quantity of clear fluid. The thorax and right side of the heart was distended with blood, which here and throughout the body was dark coloured and perfectly fluid; the left side of the heart was empty and the organ free from disease. The lungs, with the exception of a few old pleuritic adhesions, were healthy.

Intestinal Canal.—Tongue and mouth unaltered; the œsophagus was whitened and the mucous membrane so far destroyed that the muscular coat appeared to be laid bare. The stomach contained a quantity of oil, but no carbolic acid, the epithelium was destroyed, and there were signs of severe inflammation, not uniform but in spots, especially along the greater curvature; several of these spots, about the size of a fourpenny-piece, were of a deep black red, appeared almost charred; the duodenum and upper portion of the ileum were thickly coated with cast-off epithelium and mucus.

The other organs, including the brain, appeared quite healthy.

◆

REMARKS ON "RECENT REPORTS ON CHOLERA."

By Thos. Whiteside Hime, B.A., M.B., &c.,

Lecturer on Obstetric Medicine and Diseases of Women and Children, Sheffield School of Medicine; Medical Officer to the Hospital for Women; Surgeon-Accoucheur to the Public Hospital and Dispensary, &c.; Translator and Editor of Prof. von Pettenkofer's "Cholera: How to Prevent and Resist It."

Having read the series of articles on cholera in the Medical Press and Circular, I am anxious to be allowed to make some remarks suggested by their perusal. The last of the series, to which I more particularly refer, is headed "III.—Conditions of Transmissibility," and is especially devoted to the effects of impure water, of the elevation of the ground, and of personal predisposition upon the prevalence or transportation of cholera. The writer is a strong believer in infection by means of impure water, but adduces very unsatisfactory evidence in support of his opinions. One would hardly have anticipated a resuscitation of the Broad Street pump; yet here we find it trotted out as the writer's *cheval de bataille* at the head of his forces. As he evidently does not think it used up, I beg leave to refer to it also, it is to be hoped for the last time. Dr. Snow may be said to have given birth to the drinking-water theory in the year 1854 at Golden Square, in London; not but that this theory had many times previously made a struggle for life, as we find that in the good old times when every plausible organ of plague, pestilence, or famine had been adduced in vain, it was usual to fall back on the theory that some witch or enemy had poisoned the wells. Undoubtedly the London water supply in 1854 was very bad, and it had undoubtedly been so for years. In September, 1854, a severe outbreak of cholera in the neighbourhood of Golden Square led to an inquiry as to its origin. This was not far to seek. Seeing that many victims of the plague had lain for nigh two centuries in the soil below, what could be more natural than to charge them with producing the epidemic? But it subsequently appeared that the cholera showed no special predilection for the old plague district, and so another theory was wanted, but not for long. These two theories were warmly supported, but not wholly on scientific grounds, as the official report says parties interested in diverting public opinion from their own particular nuisances were loudest in proclaiming that either the pump or the long-departed dead were alone guilty. The pump theory, however, quite put a damper on the other. Seeing that two ladies who lived in a district where not a case of cholera had occurred took the disease and died, and that they drank water from the Broad Street pump, around which cholera was bad, is it not self-evident that these ladies took the disease from the water? Such is the theory. But, it may naturally be asked, how did the water get from Broad Street to the healthy district of Hampstead every day? Is it not just as possible and as probable that the cholera poison was carried by the water-carrier as by the water? The fact is, the water was brought daily to Hampstead by a gentleman who lived there with his mother, and went to Broad Street every day to his place of business, which was attacked, like so many other places in Broad Street, by cholera, and he was thus actually brought in contact with the disease every day, and passed to and fro between the infected and the healthy localities. Now, it is most unreasonable to assume that the poison was conveyed in the bottle of water rather than by the gentleman who was thus in daily communication with the infected locality and persons; and especially so as we know for a fact that in numerous other instances the poison has been thus conveyed to distant places when there was no question whatever of a possibility of water contamination. These facts stand in the published report, and he who runs may read them and compare them with the utterly unfounded conclusions which have been drawn from them. The article in the *Press* to which I have referred, and which appears in all the power of editorial type, states that "striking illustrations of the power of impure water in disseminating" cholera are to be found in the American Reports. The illustrative case extracted from the Reports is not, however, to my mind, at all convincing, and I may say that I have carefully gone through every case in the Reports without much more satisfactory results. If the reader will turn to the index of the Reports and look up the references under "Water, its Agency in diffusing Cholera," he will hardly close the book convinced of the fatal power of water in disseminating cholera, unless indeed he was convinced beforehand. Many of the cases referred to under this heading have really nothing whatever to do with water. For instance, the case of the Nashville Penitentiary is referred to as one in point; yet the only reference to impure water in the Report is that the three prison wells had long been closed before the epidemic, and the ordinary city water supplied instead. Indeed, there was serious doubt among the medical men on the spot as to whether the disease was cholera or not! In another instance the Report says of the cases which the index tabulates under "Water, its Agency in Diffusion of Cholera": "These cases were regarded by Dr. Linthicum as being sporadic in character, produced by the filthy location and habits of the individuals, the miserable food which they ate, and the impure water which they drank" (p. 134). Many similar instances will be found in the Report of the agency of water in producing cholera!

The case of Lebanon, Ky., is especially selected by the editor in the *Press* as "a striking illustration" of the water theory. Unfortunately, however, he does not give his readers the benefit of the original report, but quotes an abstract of it made to prove that the epidemic in question resulted from the use of impure water. *Hincæ ill lacrymæ.* Reference to the original Report will show the following to have been the main features of the epidemic: Cholera existed in the neighbouring Taylor County, a workman on the Railway near Lebanon contracted the disease there, and "communication was constant between the two sections [of railway ?] and the town of Lebanon." Many cases of diarrhœa followed this case of cholera. Within three weeks another case of cholera occurred in Lebanon, fatal in ten hours, contracted in Taylor County. The patient had gone there to nurse her son, and brought him back when convalescent. She was attacked the day after her return from the infected locality, and her excreta were thrown on the ground round her home. Several cases followed this in the neighbourhood. From this date, Aug. 18th, up till the 26th, when the annual fair was held, other cases occurred. But so far not a word is said of water-contamination. The source of infection has been quite clear in the small number of cases, the history of importation is distinct, and no water-spirit is required as a *Deus ex machina* to account for the disease.

The fair of Lebanon was attended by many visitors from surrounding districts, in some of which cholera already existed, as it had already done for some time in Lebanon. During the 26th, 27th, 28th, and 29th of Aug. the fair went on, crowds attending it. In the night of the 29-30th, 13 cases of cholera occurred, 12 of which ended fatally within ten hours, and the 13th some days afterwards. Supposing not a drop of water had been drunk, would the occurrence of an epidemic under these circumstances have been surprising? Crowds of people, many from infected localities, attend a fair in an infected town. During four days the fair proceeds, and we may suppose without any diminution of the excesses *in potu et venere*, &c., usual on such occasions. Would it not be regarded as miraculous if an epidemic of cholera had not occurred under these circumstances? But it appears that the water-supply on the fair ground being insufficient, an additional supply was laid on from a well situated near some infected houses. And the argument is that this water produced the outbreak among the visitors! And this, although the locality has been shown to have become infected quite independently of this water, although many of the visitors came from districts already infected, although for several weeks cholera had existed in Lebanon itself, and although in this very epidemic there are related cases which could have had no connection whatever with this water, as it was not in use at the time of their occurrence. I think I need proceed no further to show how untenable is this "striking illustration" which has been introduced from America. The line of argument adopted on this subject is usually most inconclusive, a very *opprobrium medicorum*: an epidemic (*e.g.*, of typhoid or cholera) occurs, the people are found to have a very impure water-supply, in every case investigated the water was bad (*i.e.*, all the inhabitants drank the same water), therefore the water caused the disease. Yet the water may have been as bad or worse for years without a single case of disease being attributed to it, and the vast majority of the public may be employing the same water without any ill effect. In Munich typhoid is actually worse when the water is proved by analysis to be purest! And as a matter of fact, epidemics wane and disappear while people continue to use their impure water, just as well as when a local board inspector has proclaimed that the dirty well must be closed. Indeed, in the Registrar-General's Report for 1854 we find it actually stated that the Chelsea Water Company, which drew its supply from the same point as the notorious Vauxhall and Southwark Company, only produced a mortality of 54 per 10,000, although the latter company was blamed for producing the enormous mortality of 130 per 10,000 owing to the impurity of its water! We remember what an impression was made at the time by the statement that the drinkers of the Lambeth water only died at the rate of 37, whereas the drinkers of the S. and V. died at the rate of 130 per 10,000, the Lambeth Co.'s water being from a purer source than that of the S. and V. Co.'s. And yet the drinkers of Chelsea water, according to Dr. Thompson the worst of any, drawn from the same place as the S. and V., only died at the rate of 54 per 10,000! How is it conceivable that the same water caused the frightful mortality of 130 per 10,000 when delivered by the S. and V. Co., and only 54 per 10,000 when delivered by the Chelsea Co.? Numerous other instances could be quoted to the same effect, and the converse side can be also maintained, viz., that with the best water-supply typhoid may be very bad. In the evidence given before the Health of Towns Commission, it is stated that while the water-supply of Liverpool was extremely good, the death-rate from typhoid was higher than in almost any place in the kingdom, being 1 in 407, as compared with 1 in 690 in London (which at that time had very bad water), and 1 in 917 in Birmingham. Sheffield offers another striking illustration. Its water supply is excellent in quality; *every home* is supplied with a tap from the main, and the quantity is fairly good, twenty gallons per head daily. The water is not stored anywhere in the town, and yet in the past five years there have been 991 deaths from fever, which implies the occurrence of at least 9,910 cases! With the same water the fever varied in the consecutive years as follows:—

1871. Deaths from fever, 221
1872. „ „ „ 233
1873. „ „ „ 237
1874. „ „ „ 192
1875. „ „ „ 105

and within the same year the deaths vary from 38 in a quarter to 68, in another from 59 to 90! If the water is an essential factor, how is it that while the water in any given case does not vary, the prevalence of fever varies enormously? But I have never seen or heard of any evidence to show that mortality or prevalence of cholera or typhoid varies in the same place according to the impurity of the water, as analysed for a number of consecutive years. Unfortunately, the upholders of this theory are so ready to change front that it is almost impossible to bring the question to an issue. If the water cannot be plausibly blamed, it is said to be dirt, or overcrowding, or heavy rain, or drought, or some one of the innumerable causes so ready at hand. Are there not above all the privies and ash-pits always at hand upon which to throw the blame, even though for years they stink and produce no specific fever! And is there not Prof. Gairdner, of Glasgow, a standing proof of the criminality of house drains! Has he not found a leaky drain in the case of every house visited by fever which he has examined, and has he not exhibited samples of the defaulting pipes? Of course when the houses have no drains or pipes it is just the same. It is their absence which in these cases produce the disease! But this kind of procedure is not likely to advance sanitary science or save life, however it may breed a false security. A *vera causa* is one the reality of which we are not at liberty to assume to-day and ignore to-morrow. If sewage contaminated water, dirt, overcrowding, &c., are *per se veræ causæ*, individually or collectively, they cannot be admitted to act as such in some cases only and not in others. This theory involves the further difficulty of the spontaneous origin of such diseases as typhoid. If *typhoid* is a specific disease, produced by the action of a specific organic poison, as commonly assumed, its production by drinking water containing sewage which is free from the specific poison is inexplicable. And yet there is strong evidence of the specific character of the disease.

The drinking-water theory further *assumes* that the specific poison of cholera is contained in the alvine excretions. Of the truth of this assumption there is not a tittle of reliable evidence, and there is very strong evidence to show that in the great majority of cases it does not exist in them. If it did we would find, *e.g.*, nurses, students, medical men, scavengers, and others who are brought much in the way of the patients, suffering more than others. But as a fact they do not do so. And as a death-blow to the theory I would refer to the Report of Cholera in the Prison of Laufen, issued by the Cholera Commission of the German Empire (*a*). I have extended this article to a great length, but yet space is wanting for even mentioning much weighty evidence. The subject is of the most paramount importance, and for too long its natural difficulties have been darkened by the fabulous legends of imaginative theorists. One word in conclusion. The American reports contain multitudinous references to the stamping out of cholera by "disinfection," all kinds of substances having been used. Now either American cholera is very different from European, or else our American cousins are many generations ahead of us in knowledge of how to use disinfectants. Cholera was never so fatal in Germany as in 1866, when disinfectants were most used; and in England few would venture to suggest we had found the specific antidote. Its nature and use seem however familiar to everyone in America. Heaven grant the Sun of Sanitary Science may be rising in the West!

THE VIVISECTION BILL.

The Metropolitan Counties Branch of the British Medical Association hold a meeting last week, at St. George's Hall, for the purpose of considering the provisions of the Vivisection Bill. Mr. Jonathan Hutchinson, the President of the branch, occupied the chair, and there was a large attendance of members of the profession. The Chairman, in opening the proceedings, stated that in his opinion the bill was the result of exaggerated statements which had been circulated on the subject of vivisection. The Home Secretary had intimated that the government might consent to modify the bill in some respects, and he considered that the meeting should press for the amendment of certain clauses of the bill. He alluded in detail to the chief features of the measure, particularly alluding to the fines of £50 and £100 respectively for the first and second offence of performing experiments without a licence. The method of appointing inspectors and their status required ot be defined. The registration clauses required to be modified, because as they at present stood they would retard the progress of science in this country. It would be for the meeting to consider whether it would be desirable to obstruct the further progress of the bill. They must approach the discussion of the subject in a judicial tone apart from all angry feeling, and making due allowance for the feelings of the opponents of vivisection, which were due chiefly to ignorance of the subject. The profession simply desired the advancement of science, and for that purpose alone they desired that vivisection should be continued without undue restriction (cheers).

Dr. Andrew Clark moved the first resolution:—"That this meeting, although fully recognising the improvements effected in Lord Carnarvon's Cruelty to Animals Bill in its latest form, is still strongly of opinion that, should it become law, the progress of science will be most seriously hindered, and the interests both of animals and of men much prejudiced." He said that he did not think that this was a time to mince words with the enthusiasts who supported the bill. If parliament deemed it advisable to accede in this instance to the wishes of noblemen, sentimentalists, and fanatics, most of whom indulged in cruelty in sport, the result would be that, so far as the science of physiology was concerned, England would lose her place among intellectual nations (hear, and cheers).

Dr. Pavey seconded the motion. He strongly urged the removal of the restrictions as to cats and dogs, which he deemed to be animals essentially necessary as subjects for experimental physiology. He complained strongly of the way in which some of his personal experiments had been distorted by a writer in the *Telegraph*, in order, as he alleged, to make them fit certain views advanced to which they would otherwise have been entirely inapplicable.

Dr. Wynn Williams described certain experiments on guinea pigs for the purpose of trying the effect of iodine in connection with blood-poisoning, and which, if the bill now before parliament had been law at the time, he would not have been able to make.

The resolution was carried with one dissentient.

The second resolution, "That this meeting would urge upon the promoters of the bill that legislation on this subject should be abandoned for the present session," was unanimously adopted. A considerable amount of time was spent over the third resolution moved by Mr. Gay, and seconded by Mr. Adams. Dr. Hare strongly urged upon the meeting, not to tie its hands by offering "suggestions or alternative measures" for the consideration of those who might think future legislation needful, and above all he would make no reference whatever to Dr. Lyon Playfair's bill, which it was now seen was bad and ill considered. Mr. Hogg, as strongly, objected to any extension of "Martin's Act" which was badly conceived and drawn, and was certainly passed during a period of excitement almost as great as the present, and when all kinds of calumnious statements were made against French physiologists. Dr. Pye Smith spoke in a similar strain, whilst other speakers recommended the abandonment of

---

(*a*) See a notice of this "Cholera-epidemic in der K. b. Gefangenanstalt Laufen," by me in the *Sanitary Record*, Sept. 18, 1875.

the resolution. Ultimately the conclusive and argumentative speeches of Dr. Wilson Fox and Mr. Simon prevailed, and this resolution was adopted in the following modified form, viz.—"That in the event of its being thought necessary to propose legislation on this subject in the future, this meeting would suggest as alternative measures (1) an act of simple registration of persons licensed, or (2), applicable to cruelty of all forms to all animals.

Upon the motion of Dr. Quain, a deputation was appointed to wait upon and present the resolution to the Home Secretary, and the meeting was brought to a conclusion at a very late hour, by the usual vote of thanks to the Chairman.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 2, 1876.

MILITIA SURGEONS DISESTABLISHMENT AND DISENDOWMENT WARRANT.

No act of the Government can call for stronger condemnation than the measure of spoliation entitled "Royal Warrant—Medical Officers of the Militia." Though "by Her Majesty's command," we are quite sure so generous a lady and wise a Sovereign could be no party to dealing so unjustly with a number of medical men. By its enactments the militia surgeon whose regiment is at a brigade depôt or army station ceases to attend the permanent staff, ceases to inspect recruits, and ceases to attend the preliminary drill, his allowance for medicines also ceases; his income, which may be estimated at from £150 to £250 a-year from these sources ceases therefore altogether. Provision is also made in this warrant that militia surgeons who wish to avail themselves of the "advantages specified in our present warrant!" must signify their desire to be placed in a departmental list to serve under the direct supervision of the Director-General of the Army Medical Department; the militia medical officer is to rank inferior to the army medical officer without reference to seniority, and it is specially enacted that he shall not have any claim to pension, and that the present holders of office shall also be the last on retiring allowance. And in exchange for all these *advantages* the militia surgeon is in future to be styled surgeon-major, and to receive 2s. 6d. a-day additional pay, viz., £1. It must be remembered, however, that with a few exceptions the militia surgeon-majors are to be employed only for the twenty-seven days regimental training, so that the actual increase of pay amounts to £3 7s. 6d. a-year, not a very munificent exchange for the £200 a-year confiscated!

It is incredible that so monstrous and unjust a measure should be even thought of by the War Office, more particularly at a time when candidates cannot be induced by special, though fallacious, bribes to enter the army medical service. Breaches of faith such as this new warrant it is that makes the army medical department so unpopular and deters men from entering it.

Militia surgeons hold their appointments for life, and in order to devote themselves altogether to the service, and derive the full advantages of their position, they have relinquished other and lucrative appointments and moved their residences to the head-quarters of their regiments, in accordance with the rules of the service, and relying on the permanency of their position and its emoluments, have not sought for other sources of income. No incapacity to continue their work is assigned nor any other cause for this cessation of their duties and stoppage of pay. We believe such a despotic act as this of the war office is unheard of, but we believe also that its exaggerated injustice will be the very means of procuring its withdrawal—it needs but for the country to be made aware of its confiscating nature to ensure that Parliament will deal with the warrant as it deserves. This warrant should be either at once withdrawn or ample compensation granted for loss of income; when proctors were discontinued the existing ones were compensated; army agents were amply compensated for loss of their business, militia adjutants received a compensation to give up their posts, the Irish Church received compensation. It is almost inconceivable that a department of the Government should have power to deprive a class of public servants of their income without any cause whatever. This matter should be at once brought before the House of Commons, with a view to its rectification. Mr. Hardy in the House stated long ago that individual cases would be considered, so we may infer that even he himself was of opinion that this act of spoliation should carry with it also compensation. It would be well also that an influential deputation should wait upon the war minister and obtain redress. No time is to be lost as Parliament will soon cease its sittings, and once Parliament is over no further trouble can accrue to the responsible ministers until next session. We are slow to regard this disestablishment and disendowment of the militia surgeon as originating with the present Government, and we feel confident that when the eyes of the cabinet are opened to its full meaning, ample compensation will be immediately granted to the unfortunate sufferers.

◆

THE PHYSICAL PSYCHOLOGY OF CRIMINALS.

III.

PROFESSOR BENEDIKT attaches great importance to the fact that in the four brains he examined the cerebellum was not covered completely by the occipital lobes of th cerebrum; but independently of the small number o examinations made, this observation loses a good deal of its significance from the circumstance that we are not informed whether or not this abnormity was owing to an actual atrophy of both the grey and white substance of the posterior cerebral lobes. Perhaps we cannot predicate either a low or high form of cerebral organisation from the mere position or shape of certain parts of the brain. In some of the higher Quadrumana the cerebellum is almost if not quite as much covered in by the cerebrum as it is in man; but as we cannot infer from that circumstance that the posterior cerebral organisation or power of those animals (whatever that may be) is on that account equal to what it is in man, so we cannot infer that the mere and partial uncovering of the cerebellum in some members of the human race necessarily presupposes a cerebral development which approximates to that found in brutes. If it be shown that this exposure of the cerebellum is owing to an actual deficiency in the development of the posterior cerebral lobes, their convolutions being smaller, fewer, more shallow, and the layer of their vesicular matter much thinner than natural, and, further, if this abnormity is shown to be common in murderers, while it is seldom or never noticed among the non-criminal classes, then a strong case will be made out in favour of the opinion that a decided and easily demonstrated deficiency of cerebral organisation lies at the foundation of the evil propensity of murderers and other great criminals. Until, however, this evidence be forthcoming, we must, to say the least, regard the views of Prof. Benedikt as founded upon too slight a basis to meet with the general approbation of the profession.

But admitting as we do that all mental phenomena, including will and consciousness, are, both in their normal and abnormal manifestations, greatly determined by those physical conditions of the brain with which they are so intimately connected, let us consider whether a more extended investigation into the physical psychology of criminals is at all likely to corroborate the views of Prof. Benedikt; or whether, on the other hand, we shall not rather find that the peculiar cerebral constitution, or the peculiar functional disturbance in the brains of criminals is probably of a much too subtle or too evanescent a nature to admit of recognition after death—to say nothing of the possibility of diagnosing the existence of criminal propensities during life. In such an inquiry we shall be assisted by a brief reference to what is at present known respecting the anatomical structure and functions of the brain by a consideration of certain circumstances connected with the morbid anatomy of that organ, and also by taking into account the often complex nature of the mental phenomena and impulses by which great crimes are prompted.

In the first place our present knowledge of the anatomy and physiology of the brain is not such as would lead us to suppose that any marked alteration in the conformation of the brains of murderers (presuming that such exists) would be found in any one part of the brain more than in another. As we have seen, the German Professor says we know that "the most anterior part of the brain is the seat and source of ideas, the middle part the seat of psychical action in a motor sense, and the most posterior part is the seat of sensations and feelings." But this proposition is neither a very clear nor correct statement of the case. All we can say with any certainty is that the cortical layer of the cerebrum is the instrument of all those psychical operations which we include under the general term *intellectual*, whilst (and this is of great moment in our present inquiry) it also affords, in part at least, the instrumental conditions of *emotional* states; and at the same time gives origin to all those muscular movements "which result from *voluntary* determinations, or which are directly consequent upon *emotional* excitement." With the functions of the sensory ganglia and of the cerebellum we have nothing to do, as no one would assign to those portions of the brain faculties which can in any way determine to the commission of great crimes. Now if there are some mental operations more than others at the foundation of great crimes they are certainly those *emotional* states of the mind of which we have just spoken. Consciousness, Sensation, Intelligence, Reason, are to the criminal but means to an end. They have but little connection with those impulses under the influences of which he commits the crime. They may control or even altogether overcome the criminal impulse, but they have nothing to do with originating it. They may even act in concert with it, or in direct opposition to it, as we often see a struggle between reason on one side and the criminal impulse on the other. It is therefore the emotional states of the mind with which we are principally concerned; but although most physiologists have assigned to the cerebrum the almost exclusive seat of the emotions, no one has given the slightest proof that they are located in one part of the cerebrum more than in another. Consequently we are quite at a loss to fix upon any portion of brain in which we might expect to find any difference of conformation between the most hardened criminal and the most exemplary Christian. If, on the other hand, we could place our finger upon this or upon that spot, and say here is the seat of all forms of emotional excitement, or of all those instinctive faculties which are common to man and brutes, then we might hope that an investigation into the physical pyschology of criminals might lead to such a discovery as would establish a connection between the criminal impulse and certain physical conditions of the brain. But our hopes of making any such discovery grow more faint when we reflect upon the subtle and recondite nature of the organisation and functions of the brain, and consider how much this delicate organisation may be put out of gear without leaving behind any changes that the most powerful microscope can detect. But to confine ourselves for the present to anatomical considerations, we may observe that although our knowledge of the functions of different parts of the brain is at present in its infancy, we do know that, taking the great divisions of this organ, there are certain important and very dissimilar functions which may be respectively assigned to them. That the grey or vesicular matter of the brain generally—that is, of the cerebrum, of the cerebellum, and of the sensory ganglia—is the great anatomical seat of the mental faculties, of sensation, of consciousness, and of the cerebral reflex and automatic actions (the white matter merely acting as a conducting medium between one part and another); that to the grey matter of the cerebrum may be attributed the highest and noblest of man's mental faculties as well as those great psychical functions which give him such a remarkable predominance over the lower animals; that to the grey matter of the cerebellum is, among other functions more or less unknown, assigned what has been called the "muscular sense," and the faculty of directing and co-ordinating muscular movements; and that lastly the grey matter of the sensory ganglia is the great seat of sensation for external impressions, of certain reflex actions, and probably sensation of consciousness for changes in the cortical substance of the cerebrum—all these positions are among the best established facts of physiological science. And yet, as far as the human eye, even when aided by the microscope, can reach, what a uniformity of structure do we, comparatively speaking, see in all this vesicular matter, so variously endowed with functions ranging in scope from that which we see in the most gifted of the human species to that which contracts within the narrow compass of a fish's brain. Mr. Lockhart Clarke has very carefully investigated the structure of the cortical substance of the brain, and yet neither he nor any other physiologist has described any marked difference of structure between the vesicular matter of one part of the cerebrum and that of another, between that of the infant and that of the adult, or even between that of man and that of the higher quadrumana. We admit that the arrangement of the grey matter with respect to the white matter is different in the sensory ganglia to what it is in the cerebrum, and in the cerebellum to what it is in either of those parts; and we admit also that a section of the grey tissue of the cerebellum presents under the microscope a somewhat different appearance to that presented by a similar section of the cortical layer of the cerebrum. But, nevertheless, the minute organisation of grey matter is everywhere very much the same, the difference being only such as can be recognised by the aided eye, and that difference by no means in proportion to, or sufficient to account for, the vast difference of functions with which those parts are respectively endowed. In the cortical layer of the cerebral hemisphere the structure appears to be everywhere the same, although probably (and in fact there is some proof for the assertion) the functions of the anterior lobes are not exactly the same as those of the posterior lobes. No one would say that the cerebral functions and brain power are alike in the infant, in the adult, in the savage, and in the ape; and yet neither age nor race appears to effect any visible alteration in the minute anatomy of the vesicular matter of the brain. The convolutions are deeper and more undulating and the layer of grey matter thicker in the adult than in the infant, and in the European than in the savage, but that is all; and what is still more remarkable, Mr. Lockhart Clarke has, after a careful examination, failed to find any difference between the vesicular matter of the convolutions in man and that of the convolutions of the ape tribe. Now the argument which we wish to draw from the above facts will be sufficiently apparent. For if such a variation in the functional nature or power of certain parts of the brain, or of different types of brain, is not inconsistent with little or no visible variation in the minute organisations of this organ, can we expect that the little variation of cerebral constitution which would suffice to account for difference of personal character, or for the sway or control over criminal impulses, would be attended by such marked alterations of conformation or structure as would not only be recognisable by the naked eye after death, but might, by impressing upon the cranium a peculiar contour even be recognisable during life?

ARCHEBIOSIS: A PHYSICO-CHEMICAL THEORY OF FERMENTATION.

A PHILOSOPHER and pioneer in scientific research, Robert Boyle, said—"He that thoroughly understands the nature of ferments and fermentations shall probably be much better able than he that ignores them to give a fair account of several diseases (as well fevers as others), which will perhaps never be thoroughly understood without an insight into the doctrine of fermentation." At that distance of time, now nearly two centuries ago, Boyle seems to have uttered a truism, and foreshadowed a theory which has been adopted and diligently promulgated under the generic term of "zymotic." Dr. Farr adopted the term from a belief in a supposed relationship or parallelism existing between zymosis and fermentation. The theory, however, appears to have had some share in laying the foundation for the sounder views subsequently entertained by Liebig of a physico-chemical theory of fermentation, now promising to bear good and sound fruit in the hands of Bastian. Something like twenty years have passed away since Liebig regarded a ferment as a portion of organic matter (not necessarily living), but in a state of molecular change or "motor decay," which by virtue of its own unstable nature was capable of communicating molecular movement, and thus of inducing chemical changes in fermentable matters. This theory was broached at a time when the association of low organisms and the processes of fermentation and putrefaction had no existence in men's minds, and when views of the kind would give no support to a germ theory of disease, and which by the investigations of Pasteur has been seized upon by his imitators and followers and widely adopted. The far broader, and, as we think, the truer view of the question entertained by Liebig, since so admirably worked out by Dr. Bastian, has now received very great support from researches which especially illustrate the physico-chemical theory of fermentation and conditions favouring Dr. Bastian's theory of archebiosis in previously boiled fluids. A few weeks ago, in a communication to the Royal Society, Dr. Bastian clearly proved that if liquor potassæ be added to urine in definite proportions, both before and after boiling, the same results were induced, fermentation in otherwise barren fluids, as well as those in which unaltered urine ferments under the influence of high generating temperatures (122° F.). His experiments point to but one conclusion; they show, as former experiments of his have unmistakably shown, that an exclusive germ-theory of fermentation is untenable, and not to be relied upon, and that living matter does originate independently during the progress of fermentation in previously germless fluids. On the other hand, they show that the influence of oxygen in promoting fermentation is decidedly more potent than any diminution of pressure which is brought about by hermetically sealing the vessel before the fluid within has ceased to boil. Temperature is therefore an important factor, and also, as to whether infusions are neutral or otherwise, in all of these experiments. So that had some of Professor Tyndall's infusions been rendered neutral by the addition of a small particle of alkali, it is possible, even under a "searching beam of light," that organic germs might have been discovered, although we maintain, and there are not a few skilled microscopists who can bear out our assertion, that freedom from turbidity does not mean absence of living organisms. On the other hand, we have witnessed a repetition of Professor Tyndall's experiments—solutions prepared as he directs and kept carefully excluded from contact with the outer air, in which fermentative and putrefactive changes—turbidity and bacteria—have taken place, the turbidity of the fluids being due to living organisms, and "potential germs" growing and multiplying as living things do. Dr. Bastian has, moreover, satisfied himself that fermentative changes take place in boiled urine, as well as in other complex organic solutions, forming new chemical compounds, and giving off gases, which with other suitable products mix imperceptibly with the changing and quickening mother-liquids, while certain "insoluble matters make their appearance;" such matters are readily seen under proper conditions and with a suitable magnifying power, as specks of protoplasm—"living matter." "These gradually emerge into the region of the visible," and speedily assume well-known forms of living organisms of one or other variety of bacteria. These insoluble particles thus serve to bridge over the narrow gulf between certain kinds of "living" and "dead" matter, thereby affording a long-sought-for illustration of the transition from chemical to so-called "vital" combinations. In another page we give an abstract of Dr. Bastian's suggestive communication, and which, we believe, will be found to bear out what we have stated, and support views he has repeatedly expressed on this subject and forcibly urged upon the attention of the scientific world.

THE CRUELTY TO ANIMALS SOCIETY AND VIVISECTION.

A DEPUTATION headed by a number of members belonging to the "hysterical schoool of politicians"—the Right Hon. W. F. Cowper-Temple, the Hon. Evelyn Ashley, Mr. Peter A. Taylor, M.P., Lord Harrowby, the Bishop of Gloucester, Cardinal Manning, &c.—waited upon the Home Secretary on Friday last, to urge the Government to proceed at once with the "Cruelty to Animals Bill." The usual cut-and-dried nonsense was uttered by these inconsistent and wrong-headed enthusiasts on this as on other occasions, and to which the Home Secretary politely replied that all the Government desired to do was to hold the scales of justice between the two. They must be aware that at this period of the session it would be absolutely impossible to carry a Bill of this kind in the face of the opposition from the medical profession and the scientific world, and he was in great hopes that that opposition would not be forthcoming. It was a mistaken notion that the Bill was intended to wound the feelings of professional men, and he trusted that such notions had ceased to be entertained, for nothing was further from the intention of the Government than to wound the susceptibilities of any body. He had always held that the Government must, in order to carry any Bill of this kind, if practical and permanent good was to be got out of it, have with them the medical and scientific world, so as to show an example from this country to be followed by other countries. He had to see that day some of those medical men on that subject, and so far as he understood the cardinal principles of the Bill, he was in great hopes that they would see any opposition manifested to the measure withdrawn.

The cynical Pharasaism of those forming the deputation is transparent enough. A month hence, and most of them will be busily engaged in the wholesale butchery of half-tame birds, carefully *preserved!* that the slaughter may be the more effectually, and the cruelty of the sport more enjoyable. This may be taken as a further exhibition of "*Stupidity and Science*," so cleverly depicted in the pages of our facetious contemporay, *Punch*, and will, we trust, be taken to heart by the profession. Will the Bishop and the Cardinal, and those among the deputation supposed not to be capable of joining in the pleasures of "Cruelty in Sport," head a declaration binding themselves to eat no more of the flesh of animals killed in sport, or made more agreeable and palatable by the infliction of the cruel grazier's vivisection operations—or will they, on their own behalf, and that of their families, pledge themselves in future to partake of nothing but bull-beef and ram-mutton?

◆

Notes on Current Topics.

The Case of Charlotte Hammond.

ONE of the most remarkable features in this case is the wide difference of opinion that had been expressed with regard to the conduct of the medical officer and the relieving officer respectively. When we find the Coroner's jury praising the conduct of Mr. Fenton, the medical officer, and attaching to him great credit "for his humanity and courage in bringing the case before the public, while, on the other hand, the government inspector reverses this verdict, and says "if the conduct of the relieving officer was lax, that of the medical officer was still more reprehensible," it is evident that there must be a very grave error of judgment on one side or the other. With respect to the conduct of the medical officer we consider that he did not deserve the unqualified praise of the jury, and that he certainly laid himself open to the condemnation of the government inspector. The conclusions which the Local Government Board arrived at were in any sense:—

> "1. That Charlotte Hammond died from a complication of diseases, and not from starvation caused by inability to procure the necessaries of life.
>
> "2. That her husband, with the aid of his sons and daughters, was of sufficient ability to provide her with what she required.
>
> "3. That, from the nature of her illness, she was for some time before her death able to take very little nourishment.
>
> "The first of the above conclusions is supported by the evidence of the father, two sons, and three daughters, who all testified that there was no destitution, and that food was plentiful. In fact, Louisa Hammond, who nursed her mother throughout her illness, swore that she never wanted for anything; and Henry Hammond, the husband, swore that relief was not required.

"The second of the above conclusions is founded upon the evidence of her husband and sons, which showed that their gross earnings were about £2 16s. a week, of which £1 17s. was paid directly to the mother for housekeeping purposes.

"The third conclusion is amply borne out by the medical testimony."

They also concluded that: "If the conduct of the relieving officer in failing to make proper inquiries was lax, that of the medical officer was still more reprehensible; for it is quite clear that Charlotte Hammond was not in a fit state to be removed to the workhouse when he certified that she was able to be removed, and indeed he had previously told her daughter that she was sinking rapidly."

Now we cannot help thinking thet the medical officer was somewhat to blame in the matter, inasmuch as his certificate of death led to the conclusion that, owing to the neglect of the relieving officer, the woman had died as much from starvation as from disease. But this verdict was certainly too strong considering the circumstances of the woman, the complication of diseases from which she was suffering, and the uuanimous testimony of the family of the deceased as to the sufficiency of food and money. Indeed, we are not surprised that the Local Board doubted whether even medical relief ought to have been given to this woman at the expense of the parish, or that they found fault with the relieving officer for doing as much as he did. Shortly before her death her daughters brought her some of the luxuries of the sick. One daughter gave her money to get wine with, and took her custards, another gave her port wine, oranges, and sponge cakes, and indeed the whole family resented the imputation that there was not plenty of food at home. At all events the case shows that medical officers cannot be too particular in filling up their certificates with respect either to any period relief that may be deemed advisable or to the cause of death. It is no trifling matter to attribute the death of any one, either wholly or partly to starvation, considering the indignation that such a fact must very naturally arouse in the minds of the public; and therefore a certificate to that effect should rest upon very strong evidence, and upon a most careful consideration of all the circumstances of the case.

The Death of Mr. Wimborley in Camberwell House Asylum.

A FEW days ago an adjourned inquest was held by the Deputy-Coroner for West Surrey, at the Marlborough Arms, Camberwell, relative to the death of D. W. Wimborley, a surgeon, who died on the 13th ult., at Camberwell House Asylum. Dr. Scholfield, in corroborating the evidence he gave at the last enquiry, stated he was unable to account in a satisfactory manner for the injuries found upon the body of the deceased. Most of his ribs had been broken, and the sternum fractured. The attendants had denied having ill-treated the patient, but there were two epileptic patients who had made statements to the contrary; although this evidence, when given, could only be received with great caution. The patient, it was alleged, had conducted himself in the most violent manner, but there was room left for doubt whether he himself could have caused the injuries which were inflicted, and from which he eventually succumbed. Of the two attendants who were in charge of the deceased, one named Smith had left the establishment after giving only a short notice. The other, named Saunders, who used to watch the patient by night, was still at the asylum, and although no positive evidence could be brought against him, it was alleged that when asked by the deceased for a drink he replied by striking him in the face. The witness, in cross-examination, admitted that on one occasion he had to reprimand the attendant Smith for using more force than he considered at the time was necessary, although the patient was most violent. The deceased was so incoherent that no positively trustworthy statement could be obtained from him. After some further medical evidence had been gone into, the Deputy Coroner deemed it the wiser course to adjourn the inquiry, which was accordingly postponed till Aug. 8.

In addition to the above details, which are given in most of the daily papers, we learn that no fewer than twenty-one ribs were broken, and that previous to the death of this gentleman violent vomiting and other alarming symptoms set in. We need scarcely remark how violent the force inflicted must have been to fracture the sternum and so many of the ribs, and how very rarely injuries of such a nature are inflicted by the patient himself. We believe it is the impression of the medical officers of the asylum that these extraordinary injuries were not self-inflicted, and we shall anxiously look forward to the further evidence which will no doubt transpire at the inquiry to be held in August. Considering the very humane treatment that is now adopted in all our asylums, both public and private, we cannot but regret that such sad occurrences should now and then occur. We do not, however, see how they can ever be entirely guarded against. We cannot invariably, and under all circumstances, depend upon servants in lunatic asylums more than we can in private houses; and the first indication that the medical officers of an asylum may have of the cruel and vindictive dispositions of an attendant may, unfortunately for the credit of the asylums, be accompanied by serious and very fatal consequences. Such scandals are the more deplorable considering that the public are only too ready to take alarm and to infer that what we know to be only a rare and isolated accident, is really a common occurrence. Even the present case is described in one of the daily papers under the sensational heading: "Treatment of the Insane," as though there was any connection between the injuries inflicted upon this poor man and the treatment usually adopted at our lunatic asylums.

Increase of Diarrhœa.

THIS complaint has been unusually prevalent during the past few days. With the fruit season there invariably follows an increased fatality especially amongst children; and in London, Leeds, Hull, and one or two other large towns last week it produced most serious results. In the previous week the death-rate from this cause was equal to 3·7 per 1,000, last week it had doubled itself, there being 457 deaths, equal to 6·8 per 1,000, which is higher than any corresponding period during the past ten years. In Leeds and Hull also it rose enormously, the deaths being 6·6 and 5·3 per 1000 respectively. Both Dublin and Edinburgh appear so far to have escaped this almost epidemic rate, which is so unfortunately general in other large towns.

Action of Tartar Emetic.

The *Philadelphia Medical Times* gives a few extracts from a monograph which Dr. Angelo Mosso, Professor in the Physiological Institute at Florence, has recently published on the action of tartar emetic. He studied its effects upon dogs; the medicine being given by the stomach and by injections under the skin, or into the jugular vein. He found the emetic to act more promptly, and in smaller doses, when given by the stomach than when injected into the vein. But he says large doses given by the stomach often fail to produce vomiting, while by the vein they never do. He also states that the drug acts as promptly and efficiently upon an empty stomach as upon a full one.

After death from the emetic, the stomach and duodenum were found congested, and there was a great increase in the mucous and serous secretions. Moreover, in seventeen dogs killed by injecting the emetic into the vein, the colour of the mucous membrane of the stomach varied from violet to red. He concludes that tartar emetic usually affects the vaso-motor filaments of the vagi, and causes vomiting by local irritation.

Medical Officers and Regimental Subscriptions.

We see from the Parliamentary notices that Dr. Ward will ask in the House whether military surgeons, being no longer regimental officers, will still be subjected to deductions for band and mess subscriptions. We hope the reply will be in the negative. No other departmental officers are subjected to these stoppages, and we consider the grievance a very legitimate one upon the part of medical officers. It is just one of these irritating rules which serve to keep up a feeling of injustice. Sooner or later the military authorites must yield the point, and the sooner the better. It is a very common occurrence in India for medical officers in charge of detachments some hundreds of miles from head-quarters having to pay subscriptions towards the keeping up of a band and mess which they never see. In these days, when the value of the rupee has fallen to 1s. 6d., owing to the depreciation in the value of silver, this becomes a very heavy tax indeed.

Mr. Sclater Booth on Vaccination.

Last Wednesday Mr. Sclater Booth said in the House of Commons, he was "aware that another summons had been issued against Mr. Pearce, of Andover, for non-compliance with the Vaccination Act, and that already many previous convictions had been registered against him for similar offences. He had been informed that Mr. Pearce was a member of an Anti-Vaccination Society, which paid the fines for him. Complaints had been made that several deaths resulted in Andover from vaccination, but upon inquiry this was found to be a misapprehension. He saw no reason for interfering further in the case, but he hoped that some means might be devised whereby the due execution of the law might be reconciled with some modification of the punishment provided for its infringement.

We have not the least doubt but that before long some alteration will have to be made in the punishment of those who are so foolish and obstinate as to submit to repeated fines, rather than have their children vaccinated. It often happens that petty persecutions defeats the very object it aims at, and often fans the agitation or discontent which it is desirable to suppress. This is more likely to be the case, and such petty punishments are, perhaps the less advisable, when peculiar views are held and acted upon by only a very small minority, and when the practical adoption of such views trespasses upon the welfare of that majority. For there are always some hopes that any absurd notions or practices, entertained or adopted by a few obscure individuals, will, if treated with silence and contempt, be either gradually given up altogether, or be confined within such limits as to be incapable of doing much mischief. At all events, we think that the petty punishments inflicted upon those who wilfully infringe the Vaccination Act do really more harm than good. It is certainly open to consideration whether some modification might not be made in the punishment of these refractory individuals; and whether a part of the punishment—and that a heavy one—could not be made to fall upon the society which directly encourages the infringement of the Act. Perhaps they would not then be quite so ready to pay the fines.

We are also disposed to think that compulsory vaccination as now practised might be safely modified, and very much relaxed, *provided that* the parents of unvaccinated children were liable to a very heavy penalty in the event of their children having the small-pox, and liable to be indicted for manslaughter in the event of one of their children dying from that disease. But the whole subject is too important, and attended with too many difficulties to be discussed in this place. We shall take an early opportunity of returning to it and giving it our full consideration.

Dr. Frank Payne and Absorption of Poisons by the Stomach.

We must all allow that mistakes made by medical witnesses during their cross-examination are often very excusable, but we were scarcely prepared to hear such evidence as the following:—In the enquiry into the death of Mr. Bravo, which is now going on, Dr. Frank Payne was asked by Mr. Gorst "whether the absorbent vessels of the stomach were not, two hours after dinner, particularly active?

"Undoubtedly they would be so," was the answer.

"So that (continued Mr. Gorst) anything taken into the stomach about two hours after dinner would be more quickly absorbed than at any ordinary time, when the stomach was empty?"

"I should think it would, because during digestion the stomach contains a very much larger quantity of blood, of course, than at any other time, and the absorption takes place into the blood."

Now, every first year's student knows, in fact there are very few who do not know, that the absorption of fluids by the stomach is much more rapid when that viscus is empty than when it is quite or partially full. It has been long taught by toxicologists that "absorption of poisons by the stomach is modified by the full or empty condition of the organ. The process takes place more rapidly when the stomach is empty, or when the person is fasting." The interesting experiments of Dr. Bence Jones, M. Dupré, and others, showed that the rapidity of absorption of saline solutions from the stomach was very great. But they also showed that whereas the saline solution was absorbed in from ten to fifteen minutes, when "the stomach was empty and the vascular system in a state of aptitude for absorption," thirty to forty minutes elapsed before absorption took place when the solution was administered directly after a full meal. Nor was Dr. Payne more fortunate in the reasons which appeared to him to justify the opinion he gave, namely, that absorption would be quicker soon after a meal because "during digestion the stomach contains a very much larger quantity of blood." We all know that a full state of the blood-vessels would have the very opposite effect to that described by Dr. Payne. The laws which govern the *endosmosis* and *exosmosis* of fluids are sufficient to show this, but perhaps the old experiment of Majendie is more conclusive still. That eminent physiologist found that when he had injected a considerable quantity of water into the veins of a dog poison was absorbed very slowly, whilst if he relieved the distension by bleeding, it was rapidly absorbed into the circulation. Being, therefore aware of these and many other well-known facts bearing on the subject, we were rather surprised at Dr. Payne's statement, and cannot help thinking that in the confusion of thought incidental to cross-examination he was led to make an assertion the error of which he would, on a little reflection, be himself the first to acknowledge.

Sanitary Reforms.

The evidence of the earnestness with which sanitary reform is pushed in all parts of the country has been recently very great, and shows that much may be done to prevent an increase in our population and in our commercial industries being attended by a corresponding neglect of all those hygienic precautions so necessary to ensure the health and comfort of the community.

A few days ago a deputation from the Papermakers' Association of Great Britain and Ireland waited upon Mr. Sclater-Booth for the purpose of suggesting several amendments in the Rivers Pollution Bill, more particularly affecting the paper manufacturing trade. At this meeting one member of the deputation said that the papermakers desired to avoid the pollution of streams as much as possible. The president also said "it was gratifying to hear that the manufacturing interests throughout the kingdom were desirous that some uniform and fair provision should be passed into law, some general obligations to keep the streams from pollution. No one could suppose in a limited period of time that much good would be effected on the arterial rivers, but great benefits would arise in the upper streams, and Government hoped that they would lay the first foundation of some uniformity in the matter. No doubt it would have to be taken into consideration again in future years in another direction; but if the outline of the present Bill and the suggestions they had made could be got on to the statute book, he thought they would have accomplished an important step."

Then, again, we hear of a public meeting held at St. James's Hall for the purpose of forming a Society, to be called the Sanitary Institute of Great Britain. The Duke of Northumberland presided, and there was a numerous attendance of gentlemen throughout the country. In opening the proceedings the noble duke remarked that everybody was aware that the conditions of existence in this country had of late become very different from what they were in former times. The springing up of new communities in various districts and the enormous development of manufactories had produced a state of things unknown since the creation of the world. In many of the great manufacturing towns there was an absence of drainage, a want of paving, and a total carelessness as to the provision of a pure water supply; and even where greater care had been shown in these matters, much still required to be done. In London we lived under a dense canopy of smoke, the water came from sources none too pure, while impurities were cast into the river, which must necessarily be prejudicial to the public health. The Government were trying to deal with the pollution of rivers. There were many difficulties to be overcome, and at this period of the season there was little hope of the Bill on the subject passing. He hoped, however, it would be pressed forward next year, and the proposed Institute, of which he heartily approved, was calculated to do much good in arousing public opinion on this important question.

In the next place we hear that some important reforms are being initiated with respect to the purification of the River Wye. This fine stream has got into a very polluted state owing to its reception of the unpurified sewage from the 20,000 inhabitants of the City of Hereford. Notwithstanding this condition of the river, it is said that in some districts, as in Ross and Monmouth, the inhabitants still use its water for cooking and washing purposes. On the other hand, the villagers are more particular, "and would as soon take poison as wet their lips with a drop of Wye water."

We might also notice, if space permitted, other instances of the sanitary movement that is now gaining ground in all parts of the country; and it is evident that all classes of society are becoming more alive to the necessity of maintaining around them wholesome hygienic conditions, and are anxious to advance the reforms which the medical profession can fairly claim to have commenced.

Vaccination and Small-pox.

It is very satisfactory to find that the fanatic opposition which a few obscure agitators are raising against vaccination and the due operation of the Vaccination Act has had very little effect in thwarting the endeavours which are being everywhere made to thoroughly carry out the provisions of the Act. Nor have the obstinancy and prejudices of the opponents of vaccination led to any material increase in the prevalence of or mortality from small-pox. On the contrary, the absolute amount of infant vaccination has steadily increased within the last few years, and the operation is more carefully and efficiently performed; so that, as the *Times* has remarked, the children throughout England and Wales are now better protected against small-pox than at any former period. As a corollary to this fact, we have to notice the steady diminution in the mortality from the disease. Some weeks back, when noticing the last Quarterly Return of the Registrar-General, we drew attention to the fact that the total number of deaths from small-pox in England and Wales, which in the last quarter of 1875 had been 149, rose in the first quarter of 1876 to 262. This increase, however, was entirely due to the fatal prevalence of the disease in and around Manchester and Salford, where it caused 169 deaths. But for this local prevalence, the deaths from small-pox in England and Wales during the first quarter of this year would have been fewer than in any quarter since the commencement of civil registration. Equally satisfactory have been the weekly returns that have been published since; inasmuch as during the thirteen weeks which ended on the 1st July, there were three in which no death from small-pox was registered in London, while in the remaining ten weeks the weekly mortality fluctuated between one case and four cases, amounting only to a total of 26.

That the satisfactory nature of recent Reports on the prevalence of small-pox is in a great measure due to effective legislation, to the increased care and vigilance of local authorities, and to an improvement in the hygienic condition of the country generally, there cannot be the least doubt; and we are glad to see that these views are shared by those whose position gives them the opportunity of influencing public opinion. Therefore, while there are a few—and among them persons who ought to know better—raising their voices against vaccination, it gives us great satisfaction to find the *Times* admitting that our immunity from this loathsome pestilence is in no way due to any change in the malady itself; that it has really been the reward of conscientious and well-directed sanitary work; and that "it is to vaccination, and vaccination alone, that we owe whatever freedom from small-pox we now enjoy, or may hope to hand down to future generations."

Sectional Presidencies in the British Medical Association.

THE presidencies of four sections at the meeting of the British Medical Association have been distributed to two Englishmen, one Irishman, and one Scotchman. The medical section will be under the control of Dr. Chadwick, of Tunbridge Wells, and that on surgery under the care of Mr. Jonathan Hutchinson. Dr. Lombe Atthill, of Dublin, the Master of the Rotundo Hospital, has been invited to take the presidency of the obstetric section, and Dr. J. B. Russell, of Glasgow, that of the public medicine section. Dr. Atthill is the first Irishman who has been so honoured by the association for some years.

Martyrs for Vaccination.

IT is not always easy to mark the limit at which commendable perseverance merges into amazing pig-headedness, and opinions may therefore differ as to the virtues of the Keighley guardians who have earned notoriety, if not honour, by their resistance to vaccination law. If there be admiration for the spirit of the Irishman's pig who, tethered by leg, goaded by stick, and urged by persuasion, yet seeks to follow the bent of his own inclination, then there must be virtue in the valour of the Keighley guardians, and we should honour them as heroes instead of despising them as fools. Unawed by law, and unpersuaded by reason—mentally amblyopia and obtuse in judgment, they keep their own blind road, and have again refused compliance with the mandate of the law. So be it. They will go to jail, and doubtless will bate not a whit of their obstinacy when they are lodged there. How they are to get out is a serious question. The Court of Chancery always keeps its grasp upon the recalcitrant until he cries *peccavi*, which we may be sure the Keighley guardians never will. Perhaps there will be no ultimate escape from the dilemma but the covert removal of the victims, as suggested by Mr. Weller, senior to Mr. Pickwick in the body of a grand piano. Truly martyrdom is no longer saintly when it can be earned by a stupid vestry man in a contest with the law and common sense.

Election of a Master to the Coombe Lying-in Hospital, Dublin.

AT a meeting of the guardians and directors of this hospital on the 22nd ult., a vote of condolence with the family of the late Dr. Ringland, in their heavy bereavement, was passed amidst many expressions of heartfelt sympathy.

The board then proceeded to the election of a master, in room of the late Dr. Ringland, who had been master for thirty-five years. Sir William Carroll, M.D., alluding in kind and affectionate terms to his old and valued friend, the late Dr. Ringland, and to his very long and faithful services in connection with this institution, and to his eminent worth in the medical world, regretted that the time had come when they were called upon to elect one in his place to the mastership of this hospital.

He believed that in proposing Dr. G. H. Kidd he was consulting the best interests of the institution. A ballot having taken place, Dr. Kidd, who is President of the Royal College of Surgeons for the current year, was declared unanimously elected to the mastership for the ensuing seven years, according to the terms of the royal charter of the institution.

Putrid Meat.

SCARCELY a day passes but we read in the daily papers of the seizure in some part of the metropolis of meat that is bad, putrid, and altogether unfit for consumption. No long ago an enormous quantity of bad and partly putri meat was seized in a West-end shop just as it was on it way to the sausage manufacturer. As recently as the 26t ult. William Leaning, a butcher, of Barton, Lincolnshir was summoned before Alderman Nottage for sending t market four quarters of a calf that were unfit for food Messrs. Wylds and Newman, inspectors of the Metropolitan Meat Market, and Dr. Sedgwick Saunders, medic officer of health, gave evidence in support of the charg Mr. Baylis, solicitor to the Commissioners of Sewers stated that the defendant had had six weeks imprisonment for a similar offence. Alderman Nottage sentenced him to two months' imprisonment. James Gould and William Wright, of Brighton, were summoned for a similar offence in relation to the carcase of a cow. The charge having been proved, the Alderman sent both the men to prison for a month.

We can, however, form from these committals, frequent as they are, but a slight idea of the extent to which this traffic in bad meat of all kinds is carried on, or of the very large quantity of unwholesome food consumed by the poorer classes of society. We hear of those cases which are so bad that they cannot easily escape detection or the punishment which the law inflicts, but we hear nothing of the innumerable cases which escape the vigilance of the official inspectors, or of the extensive trade in the sale of meat which, although far from being fresh and wholesome, is not sufficiently bad to enable the inspectors to obtain a conviction. And yet when we consider the enormous quantity of bad meat, of bad fish, and even of bad vegetables that is sold every day in the poorer neighbourhoods of our large towns, the wonder is that we do not hear of more illness, traceable to such unwholesome food, than we really do. As a matter of fact, the poor do not suffer from these inferior and often disgusting comestibles so much as one would suppose. The prevalence of diarrhœa, the disease most likely to arise from this state of things, is found, as the Registrar-General's returns will show, to depend far more upon the temperature than upon anything else, and is also far from being restricted to the children of the poorer classes.

Perhaps the comparative impunity with which half-putrid food may in some cases be partaken of is partly owing to its being thoroughly cooked, and partly to the antiseptic properties which have been proved to reside in the gastric juice of the stomach, as well as in the bile. It will be recollected that in one of the numerous experiments performed by Dr. Beaumont, a piece of meat which had been macerated in water at the temperature of 100° for several days till it acquired a strong putrid odour, lost, on the addition of some fresh gastric juice, all signs of putrefaction, and soon began to be digested. Likewise the bile has a strong antiseptic power, and may not only prevent but arrest the decomposition of food during its passage through the alimentary canal. The experiments of Tiedemann, Gruelin, and others showed this to be the case; and it was also found that the mixture of bile with a fermenting fluid arrests the process of putrefaction.

The Late Dr. Lonsdale.

We regret to have to announce the death of Dr. Henry Lonsdale, of Rosehill, Cumberland. From the *Scotsman* we learn that Dr. Lonsdale was a native of Carlisle, where he was born in 1816. In 1834 he entered upon a course of medical education at the Univerrity of Edinburgh, where, after a distinguished career as a student, he took his degrees. Fascinated, probably, in some degree by the ability and happy tact as a teacher displayed by the celebrated Dr. Knox, he became, in particular, ardently devoted to anatomy, scientific and practical, and attained remarkable proficiency in that department. In 1840 Dr. Knox, who had survived his early popularity, felt it would be for his interest to leave the city; and Dr. Lonsdale carried on Knox's courses of lectures on anatomy, together with his demonstrations, and these he turned to excellent account in teaching his favourite science in the extra-academical school till 1846, when he made over the materials to Dr. Handyside and Mr. James Spence, now Professor of Surgery in the University. Removing about this time to Carlisle, Dr. Lonsdale settled there as a general practitioner, and meeting in that capacity with rapid success, became the chief consulting physician in that part of England. After some years of extensive and remunerative practice he married a young lady of fortune, and retired to Rosehill, an estate belonging to his wife, in the neighbourhood of Corby Castle. The subsequent years of his life were mainly devoted to literary pursuits. Besides contributing to the medical journals, he published a life of his old master, Dr. Knox, containing a great deal of curious information as to so-called "resurrection" practices; lives of Dr. Heysham and Watson, the sculptor, both Cumberland men; and other biographies of "Cumberland Worthies." Latterly his health gave way, and he suffered much from bronchitis, to an attack of which he finally succumbed.

Typhoid fever has appeared at Shottery, near Stratford-on-Avon. One death has occurred, and seven other cases are reported. The cause of the epidemic has been traced to a well, the water of which was found contaminated with sewage matter.

One of the lady students educated at the London School of Medicine for Women passed the examination in anatomy and physiology at Paris last week. The marks given at this examination are in four grades, and the highest were obtained by the lady in question, the examiners remarking that the knowledge of the subject she had shown was a proof not only of her own industry, but of the sound practical instruction which she had received.

Dr. Hooker, the President of the Royal Society, and Mr. Spottiswoode, the Treasurer, together with Dr. Burdon Sanderson and Dr. Siemens, had an interview with the Lord President of the Council, the Duke of Richmond and Gordon, on the 17th ult., and presented a memorial from gentlemen who have been connected with the loan collection of scientific apparatus at South Kensington, urging the importance of establishing a museum to contain scientific apparatus, appliances, and chemical products illustrating both the history and the latest developments of science. His Grace discussed the subject of the proposed museum with the deputation, and stated that he would consult his colleagues.

Last week's *Punch* contains an excellent cartoon entitled "Stupidity versus Science" in which Sir James Paget, Sir William Jenner, Sir Henry Thompson, and others whose faces we do not recognise, appear in a laboratory, engaged in physiological investigations with a frog and microscope before them; the operator is explaining the action of certain drugs, which knowledge, gained from experimentation upon the lower animals in times past, has been the means of saving the lives of thousands of human beings. Interrupting the demonstration a policeman enters, and as representing a *posse* of ignorant fanatics, orders the experimenters "to move on." This demand is met with the evasively sarcastic reply "that's impossible if you interrupt us." We thank our facetious contemporary for using his powerful pen to stem the tide of stupidity for science and humanity sak e

Correspondence.

ARMY MEDICAL DEPARTMENT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In your issue of to-day, you say (I am sure quite inadvertently) that after ten years' service those who now enter the army "will be allowed to retire, *if desired*," thereby leading them to infer that they can remain if they wish. This is not so. They will be all sent about their business, with the exception of six only who will annually *be selected* for retention. The rest will have to begin life *de novo*—and then, most probably, with impaired health from tropical service. But more than this, every one who is invalided under five years of actual service will be struck off the list without gratuity of any kind. He will be turned out without one shilling and no redress. These facts should be made clearly known *now* through the medium of your pages, or otherwise you may hereafter be blamed for having misstated the case in one respect, and withheld important information upon another, and thus led men into joining, when they would not have done so if they had been aware of the real facts of the case.

Your obedient servant,

July 26th, 1876. A Subscriber.

CONTAGIOUS DISEASES ACTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—As an old subscriber to your excellent paper, I hope you will accord me space in which to question the following statement which I find in your issue of July 26 :—

"The opponents of the Contagious Diseases Acts have utterly failed to disprove or to account for the immunity of the army and navy from veneral diseases which has ensued since the Act came into operation."

Now, sir, I think you will not hesitate to acknowledge that secondary or true syphilis is the most important, if not the only important venereal disease with which we have to deal; well, this serious form of disease fell off in the army without the Act from 32·68 per 1000 to 27·73 per 1000 between 1860 and 1866, the year when the existing Acts were first enforced. When the Acts came into operation the fall *was arrested* and this serious disease rose, so that in the average of the six succeeding years it was one sixteenth higher under the operation of these Acts than it was without them. This was so serious that the advocates of the Acts in order to improve the returns determined to punish soldiers who contracted disease by stopping their pay, and in other ways offering them every inducement to conceal disease. The army report for 1873, says page 13, "It is presumed that this led to concealment of disease." This effort, however, has been attended with but slight success, for the latest report, that for 1874, shows that the proportion of men affected with this serious disease under the protecting provisions of the Acts is 24 per 1000, see "Army report," 1874, page, 20.

In the home navy we don't know what was the proportion of secondary disease previous to 1866, but at that date it was 15·7 per 1000 under the protecting provisions of these Acts it attained the highest ratio recorded, namely, 18·3 per 1000 in 1872, and in the average of the whole eight years under the Acts it has been 14·9 per 1000, which is just about what it was without them. In Hong Kong the Acts have been in operation seventeen years, and the result is that true syphilis is higher than in any other station, the proportion of soldiers affected being 46 per 1000. As to gonorrhœa Dr. Balfour acknowledged before the Royal Commission, and the army reports prove the truth of the assertion that gonorrhœa has been higher at the stations under the Acts than in those not under them. As to simple non-infecting sores, this class of disease fell most rapidly without the Acts, and it has fallen slightly with them, but not *nearly as much with as without*.

The writer of the article in your journal from which I have quoted, gives us the calendar, as he calls it, of a prostitute, and assumes that there would be much less disease among these women if the Acts were enforced. Now in 1866, the year when the existing Acts were enforced the proportion per cent. of cases of disease among those women was 121, that is each woman was diseased more than once a-year, under the operation of the Acts *disease has more than doubled, and the deaths have more than donbled*, so that it does not seem likely that the calendar would be improved by the extension or maintenance of the Acts.

I am afraid, sir, that the gentlemen who write the dogmatic articles in support of the Contagious Diseases Acts with which we are but too well acquainted, are ill-informed on this matter. It is only by free discussion that we shall arrive at the truth, and I trust that your paper, will as heretofore, to your great credit, be open to advocates of both sides of the question.

Your obedient servant,

Nottingham. Chas. Bell Taylor, M.D., F.R.C.S.E.

Medical News.

Royal College of Physicians of London.—The following gentleman were admitted Members of the College on July 27th :—

Burrell, Edwin, M.D. Aberd., 20 Endsleigh St., W.C.
Dixon, Edward Livesey, M.D. St. And., Preston.
Dreschfeld, Julius, M.D. Wurzburg, Manchester.
Holland, Edmund, M.D. Lond., 1 Titchfield Terr., N.W.
Warner, Francis, M.D. Lond., Birmingham.

Royal College of Surgeons of England.—The following gentlemen, having passed the required examination for the diploma, were duly admitted Members of the College at meetings of the Court of Examiners on July 25th and 26th :—

Appleby, John T., Knutsford.
Ballard, Philip, Bromyard.
Beverley, William H., Leeds.
Blaikie, John R., L.S.A., Oswestry, Salop.
Cash, John T., M.B., Manchester.
Cattle, Charles H., Pontypridd.
Dawson, Cantley, Leeds.
Donbavand, Edgar John, Hackney.
Dunbar, James J. M., Talbot Road.
Ellis, Philip M., Chudleigh, South Devon.
Folkes, Frederick H., Dukinfield.
Gosling, Charles E., The Green, Richmond.
Harding, George C., Clapham.
James, Charles, St. Just, Cornwall.
Kilbride, James, Dublin.
Lapage, Charles C., Leeds.
Lennon, George L., Manchester.
Marsh, Octavius E. B., L.R.C.P., Cotham, Bristol.
Mercer, Robert, Bradford, Yorks.
Moxon, William, Birmingham.
Phillips, Alfred, L.S.A., Primrose Hill Road.
Phillips, Charles H., Ramsbottom, nr. Manchester.
Pratt, William, M.D., Newtown.
Richardson, Thomas W., L.S.A., Norwich.
Robinson, Ernest L., St. Martin's, Guernsey.
Routh, Jules Isham, Manchester.
Spofforth, John, Litchfield.
Sweeting, Martin C., Knaresborough.
Thomas, Abraham G., Aberayron, South Wales.
White, Alfred O., Tangier, Africa.
Wiglesworth, Joseph, Liverpool.
Williams, Charles L., Sattley, Warwickshire.

Vital Statistics.—From the Registrar-General's report w learn that during last week 5628 births and 3893 deaths we registered in London and twenty-two other large towns of t United Kingdom. The mortality from all causes was at t the average rate of 25 deaths annually in every 1000 perso living. The annual death-rate was 18 per 1000 in Edinburg 20 in Dublin, 26 in Glasgow, and 28 in London. The annu rater of mortality during the same period in the other lar towns were—Bradford 14, Norwich 14, Brighton 15, Wolve hampton 16, Birmingham 19, Sunderland 19, Portsmouth 2

Sheffield 22, Plymouth 22, Nottingham 23, Liverpool 24, Bristol 24, Leicester 14, Oldham 25, Newcastle-upon-Tyne 26, Hull 27, Manchester 28, Salford 21, and Leeds 32. The annual death-rate from the seven principal zymotic diseases averaged 7·3 per 1000 in these towns, and ranged from 1·0 and 1·3 in Brighton and Norwich, to 10·4 and 10·5 in Leeds and Portsmouth. Scarlet fever continues fatally prevalent in Portsmouth. Thirteen more fatal cases of small-pox were registered in Manchester and Salford, in addition to 2 in the Monsall Hospital. In Liverpool the deaths from small-pox were 16, against 7 and 20 in the two previous weeks. In these towns 670 were referred to diarrhœa, whereas in the three previous weeks the numbers were 88, 188, and 352, respectively; the ounual death-rate from this disease was equal to 3·2 per 1000. The highest death-rates from diarrhœa in the provincial towns were 5·3 in Hull, and 6·6 in Leeds. In London the 1878 deaths in included 8 from small-pox, 34 from measles, 35 from scarlet fever, 10 from diphtheria, 29 from whooping-cough, 20 from different forms of fever, and 457 from diarrhœa; thus to the seven principal diseases of the zymotic class 583 deaths were referred, against 245 and 373 in the two preceding weeks. The 583 deaths were 117 above the corrected average number from the same diseases in the corresponding week of the last ten years, and were equal to an annual rate of 8·7 per 1000. The fatal cases of measles, scarlet fever, small-pox, and whooping-cough were proportionately most numerous in South London.

◆

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Reading Cases.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the Medical Press and Circular, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat, after it has passed through the post.

Dr. G. will observe on reference to another column that his request has been complied with.

Dr. R. M. is thanked.

Oswego Flour.—In the contest for foods which has achieved so much importance in recent years, the preparations derived from the maize have certainly acquired and maintained a supremacy over the arrowroots and other starchy foods which were the favourites of the nurses who reared our forefathers, and the great variety of uses which cornflours can be applied to are not less in their favour than the high alimentary qualities which they possess. Of these preparations one of the best, if not the very best, is, we believe we may say, the "Oswego," prepared by Kingsford, of New York. We have personal knowledge that children thrive upon it, and the analyst who examined it for the proprietors declares that the sample which he tested was entirely pure and unadulterated. It is palatable and applicable to innumerable purposes, and the modern housewife has in such food a resource which would have been coveted by her prototype.

CONDY'S OZONIZED SEA-SALT.

To the Editor of the Medical Press and Circular.

Sir,—Will some of your subscribers who may have used *Condy's Ozonised Sea-salt* for baths kindly inform me if it is coloured or colourless. Patients object to employ "Condy's Fluid" in baths because it looks remarkable, and stains. True the stains can be taken out with oxalic acid, but this latter is highly poisonous, and might be mistaken for Epsom-salts. I think ozonized baths of great value in summer for those who can't get to the sea-side, but do not know any one who has tried the ozonised sea-salt for the purpose.

Enquirer.

[*** Our experience of Condy's Ozonised Sea-salt, though somewhat limited, goes to confirm the opinion formed by others as to its value as an invigorator and detergent. It has an analine lint, but this quickly vanishes from the bath; so that neither staining of the flesh nor clothes need be feared. We are not surprised to hear that "Condy's Fluid" is objected to in baths, we did not know it was ever used for the purpose. Perhaps some of our readers can give our correspondent the results of their experience of the ozonised sea-salt.—Ed. M. P. & C.]

ROYAL COLLEGE OF SURGEONS IN IRELAND.

At the examination in general education, held on the 16th of July, the following gentlemen were adjudged certificates of qualification, the names in the first and second classes being arranged in order of merit:—

First Class—(Thomas Butler, John Pollock, and Ignatius Joseph Rubi), equal; (William Maguire and Frederick Charles Stevenson), equal; William Hartford and Martin Sandaus Hogan.

Second Class—(William Swanson, George Elliott, Erasmus Lloyd Duke, and John Jeramiah O'Leary) equal; (Charles Vokes, Edward Corbett, Samuel M'Cutchen Cowe, David Henry Crighton, Henry Vincent Dillon, and John Neill), equal; (Daniel B. Clancy, Robert James Tate, and Macnamara Morgan Williamson), equal; (John Barry, Chas. Butcher, and Robert Warnock), equal.

Unclassed—Charles Thomas D'Arcy, William Bunbury Eames, John Wm. Goldon, Charles Henry Hartt, Gilbert Marshall, Michael M'Hugh, John Joseph Stack, Wm. Woodroof, and Charles Stackpoole.

Cancer Curers.—We have had a good many of these gentry in our midst, but happily are free of them just now. One of them seems to have turned his attention to the American public, advertising in some of the leading journals a wood-cut of a cancer with all "its roots and fibres, which he recently extracted from a patient without the aid of the knife, caustic, burning medicines, pain, or the loss of a drop of blood." The illustration has the merit of being *perfectly original.* We never saw anything like it; its extractor is Professor Kline, M.D., of Arch Street, Philadelphia, to whom we make a present of this advertisement.

Erin.—Ashpits and privies are best disinfected with dry earth, peat mould, coarse sulphate of iron (copperas), or carbolic acid. If water be allowed to get into an ashpit, or to remain there for want of a sewer, it will be always offensive.

VACANCIES.

General Medical Council. Registrar. Salary £500 per annum. (See Advt.)

Birmingham General Hospital. Resident Medical Officer. Salary £130, with board, &c. Applications under cover to the House Governor.

Birmingham Eye Hospital. Dispenser. Salary £70, with partial board. Applications to the Secretary.

Birmingham Free Hospital for Sick Children. Two Physicians for the Out-patient Department, to each of which an honorarium of £60 per annum is attached. Applications to the Medical Committee.

Birmingham Queen's College. Medical Tutor. For information apply to Dr Hinds, at the College.

Royal South Hants Infirmary. House Surgeon. Salary £85, with board and residence. Testimonials, &c., to Dr. Lake, Southampton.

Sussex County Hospital. House Surgeon. Salary £80, with board, lodging, and £10 from each of the resident pupils. Applications to the Secretary at Brighton.

Daventry Union. Medical Officer and Public Vaccinator for No. 2 District. Salary £25, with fees extra. Address the Clerk to the Guardians, Daventry, Northamptonshire.

◆

APPOINTMENTS.

Burness, Dr. A. G., Medical Registrar to the Hospital for Sick Children, Great Ormond Street, London.

Carby, R. J., M.R.C.S.E., Medical Officer for the West Ham No. 4 District of the West Ham Union, Essex.

Chadwick, W., M.R.C.S.E., Junior Resident Medical Officer to the Leeds Public Dispensary.

Cole, G. M., M.R.C.S.E., House Surgeon to St. Peter's Hospital for Stone, London.

Dougall, J., M.D., an Extra Dispensary Physician to the Royal Infirmary, Glasgow.

Leigh, T., L.R.C.P.L., M.R.C.S., an Acting Surgeon to the Brighton Hospital for Sick Children.

Thomson, J. M.B., C.M., an Assistant Medical Officer to the Southamptonshire Lunatic Asylum, Knowle.

◆

Marriages.

Geraty—Unthank.—On July 25th, Thomas Geraty, Esq., M.R.C.S.E., Nottingham, to Catherine, second daughter of Anthony Unthank, M.R.C.S.E., Nottingham.

Walsham—Spencer.—On July 26, at St. Bartholomew's, Sydenham, Edith Maria, elder daughter of Joseph Huntley Spencer, Hastings and London, to William Johnson Walsham, M.B., F.R.C.S.E., of Weymouth Street, London.

◆

Deaths.

Absolon.—On July 17, at Perth, George Webster Absolon, M.D., aged 50.

Anderson.—On July 25, at Moira, co. Down, Dr. Despard Anderson, third and only surviving son of Louis Anderson, Esq., 46 Belgrave Square, Rathmines, late County Inspector R.I.C.

Cooper.—On July 17, at Burlington Buildings, Redland Park, Bristol, William Cooper, L.R.C.P.L., aged 46.

Roots.—On July 18, at Kingston-on-Thames, William Sudlow Roots, F.R.C.S.E., aged 71.

GENERAL NURSING INSTITUTE for TRAINED HOSPITAL NURSES.

5 Henrietta Street, Covent Garden, W.C.
A. EBSWORTH, F.R.C.S., Director.

ROYAL HOSPITAL for DISEASES of the CHEST, City Road.

There being a VACANCY for a PHYSICIAN, Candidates, who must be Fellows or Members of the Royal College of Physicians of England on the day of election, are requested to send in their applications, with Testimonials, &c., by WEDNESDAY, AUGUST 9th.

C. LOWTHER KEMP,
July 19th, 1876. Secretary.

ELECTION OF REGISTRAR OF THE GENERAL MEDICAL COUNCIL.

AN ELECTION to the office of REGISTRAR to the General Medical Council, vacant by the Resignation of Dr. Hawkins, will be made by the Executive Committee of the Council in October next. The salary is £500 a year. Information as to the duties of the office may be obtained on application, personally, or by letter, to the Registrar, at the Medical Council Office, 315 Oxford Street. Applications must be lodged on or before the 20th day of September next, with Testimonials in print, of which at least 12 Copies are to be provided. Selected Candidates will, at the proper time, be invited to attend the Executive Committee, and Candidates are requested meanwhile not to canvass the Members of the Committee.

ARMY MEDICAL DEPARTMENT, 22nd July, 1876.

AN EXAMINATION of CANDIDATES for COMMISSIONS

in the MEDICAL DEPARTMENT of Her Majesty's Army will be held in London on Aug. 14, 1876, and following days.

1. Candidates having two qualifications—one to practise medicine, and the other surgery, under the Medical Act, and who are not under 21 nor above 32 years of age at the date of the London examination are eligible to attend.
2. Those gentlemen who may be selected for appointment will receive £250 per annum and allowances in addition, after passing the examination at the Army Medical School at Netley.
3. The tenure of appointment will be limited to 10 years, and on the completion of that period of commissioned service, surgeons, unless they be specially selected for further employment in the Department, will be entitled to receive, in lieu of all pension on retirement (pension for wounds excepted), the sum of £1,000.
4. Application for admission to the examination should be made in writing, without delay, to the Director-General of the Army Medical Department, London, by whom a printed schedule containing further particulars will be furnished.
5. There will be 20 appointments offered for competition.
6. The List will be finally closed on Saturday, the 5th August next,

(Signed), W. M. MUIR,
Director-General, Army Medical Department.

THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.

Patron:—H.R.H THE PRINCE OF WALES.

This Institution was founded in 1869, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develop the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £40 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote.

Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c, can be had at the office,

NOTICE.

The present rate of interest allowed on Deposit Receipts is 3½ per cent. per annum.

Depositors have the following guarantees, viz.:—

The entire funds must, under the Act of Parliament, be invested on mortgage of freehold or leasehold property.

The total amount receivable on deposit is limited by the Act to two-thirds of the balance due to the Society on its mortgages.

The Paid-up Capital exceeds £135,000.

Remittances may be made by cheque or bank order, payable to the undersigned.

Prospectuses and every information will be forwarded, post free, on application to

ALFRED H. MERCER Secretary.

GLASGOW ROYAL INFIRMARY MEDICAL SCHOOL.

The WINTER SESSION will be opened on November 1st, 1876.

LECTURES AND DEMONSTRATIONS.
Chemistry—John Clark, Ph.D.
Anatomy—H. E. Clark, M.R.C.S.E.
Physiology—W. J. Fleming, M.B.
Surgery—H. C. Cameron, M.D.
Medicine—A. W. Smith, M.D.

The Hospital contains 570 beds. Of these, 240 are for Medical cases, and 330 for Surgical cases, with a special ward for the treatment of Venereal Disease in males. Diseases of the Eye, Ear, and Throat are specially treated at the Out-door Department.

The number of In-patients under treatment last year was 5,682, and 18,876 received advice at the Dispensary.

The Museum, which is large and varied, includes an admirable series of Models of Skin Diseases.

Appointments.—There are five Physicians' Assistants, and five Surgeons' Assistants, who reside in the house. These Appointments, for which a nominal fee is charged, are open to Students who have passed all their Examinations except the last, and are held for Twelve months—Six in the Medical, and Six in the Surgical Wards. Clinical Assistants and Dressers are selected from the Students without payment; and from the large number of cases of Accident and Acute Disease treated in the Surgical and Medical wards, such Appointments are very numerous, and the advantages to the Student are unusually great.

For further information apply to Dr. Thomas, the Superintendent.

Royal Infirmary, Glasgow, July, 1876.

LINCOLN LUNATIC HOSPITAL.

(OPENED IN 1819.)

THE RIGHT HONOURABLE THE LORD MONSON, President.

THERE are a few VACANCIES for PATIENTS of both sexes in this INSTITUTION.—This Hospital was the first in England to adopt the most beneficent system of non-restraint, and that system is still carried out in the greatest perfection. The Hospital stands in its own well arranged grounds of over 8 acres, and occupies a most healthy and delightful site, the views from the grounds and building being of a most extensive character. The Hospital has an experienced Resident Medical Superintendent, and is visited by four Honorary Physicians and Surgeons. The business of the Institution is conducted by a Board of Governors which meets weekly, and regulates the terms upon which patients are admitted.

By Order, RICHARD HALL, Secretary.
Board Room, Lunatic Hospital, 1876.

IRISH POOR-LAW INTELLIGENCE.

THE ABUSE OF RED TICKETS.

Specially Reported for the Irish Medical Association.

MONAGHAN ASSIZES.

(Before Mr. Justice FITZGERALD.)

IMPORTANT APPEAL AND JUDICIAL OPINION.

WILLIAM CRUMLEY, APPELLANT; WM. WOODS, M.D., RESPONDENT.

THE case reported briefly in our issue a fortnight since, was brought before the judge at assizes in Belfast last week. The secretary of the Irish Medical Association had brought the case under the notice of the Committee of Council, who considered the principle involved so important to the dispensary medical officers of Ireland as to deserve the active interposition of the Association in aid of Dr. Wood's claim, and accordingly the Committee of Council authorised Dr. Woods to obtain the services of leading counsel at the expense of the Association, for the full argument of the subject before the judge if considered necessary.

This was an appeal from a decree given by the chairman at Quarter Sessions to compensate Dr. Woods for professional attendance on, and services rendered to, the wife of one Bernard M'Geough, a national schoolmaster. Dr. Woods is the dispensary medical officer for Monaghan, and received from M'Geough a red ticket, issued by the appellant, requiring him to attend the wife of the former in her confinement. M'Geough had a salary which, with his wife's, amounted to an income of, on his own showing, about £70 a year; and this being so, Dr. Woods, after having successfully treated the case, attended at the following meeting of the Dispensary Committee, and had the ticket cancelled six days after its issue.

Dr. Andrews, in stating the case for the respondent, said it was one of considerable interest, and revealed a state of things which, if permitted to continue, might have a considerable effect upon the poor-rates of the union, as well as upon individuals. It was a case which was brought by Mr. Wm. Woods, medical doctor, against Wm. Crumley. Mr. Crumley was a publican residing in Monaghan, and during the years 1874-5 he was a poor-law guardian of the union of Monaghan, and, as such, ex-officio member of the Dispensary Committee of Monaghan. The details of the case would show that during his years of office he did not take much trouble in attending the meetings or in the exercise of the powers which membership conferred upon him. In connection with each dispensary there are ticket-books issued to the members, one being a black ticket and the other a red one. The black ticket entitles the person receiving it to attend at the dispensary and receive medicine gratis from the medical officer. The red ticket requires the medical officer to visit the patient at the patient's home, and the terms in which the order in the ticket is couched amount to a command, for the medical officer is "required" to do so. Council then referred the court to the Medical Charities Amendment Act of 1851, the 9th section of which applied directly to this case, and authorised the issue of tickets. There were twenty-seven or twenty-eight members of the Dispensary Committee, and if they had all acted in the same reckless manner in which Mr. Crumley acted, it would have had a swamping effect, not only on the rates of the union, but would impose such an amount of labour on the medical officer as it would be impossible for any man to attend to. The provisions of the several acts, and the powers vested in the Dispensary Committees, were all contained in the orders issued by the Local Government Board in 1870, and embodied the following directions to persons issuing red tickets: "The ticket and counterpart are both to be filled up by the person authorised to issue the ticket, one part to be retained by the party issuing the ticket, the other to be detached from the book and given to the applicant for presentation to the medical officer. Care should be taken in issuing the ticket accordingly; and tickets should be issued, for visitation at the residence of the applicants, in cases of necessity only, and with all available information as to the nature of the case. Care should be taken to fill up the ticket, as well as to apprise the applicant that the medical officer of each dispensary district is only bound to attend any poor person resident within the dispensary district." The instructions of the Local Government Board further went on to show that if the medical officer have reason to believe any case to be an unfit one for the continuance of medical relief, it is competent for him at any time to report the circumstance of the case to the committee for their directions. The special attention of the Dispensary Committee was requested to the 14th and 15th Vic., cap. 68, which enacts that a ticket for medical relief continues in force until it is cancelled by the committee, and in the case of a red ticket, or a ticket (as in this case) requiring the medical officer to visit at the patient's home, the medical officer is bound to continue his attendance in pursuance of a visiting ticket, until such attendance is no longer required. The same Act also enacts the ticket must remain in full force till a majority of the committee, present at any meeting, shall declare the person not to be a fit object for dispensary relief, by whom the ticket may be cancelled, and the holder disentitled to further relief. Counsel read the form of red ticket and the directions given to the person issuing it, and was proceeding to state the facts of the case when

Judge FitzGerald enquired—Wasn't this a fraud?

Dr. Andrews—Well, "fraud" is a word I don't want to import into the case.

Judge FitzGerald—Well, could it have been a mistake?

Dr. Andrews—Oh, if it were a mistake, my lord, I should not be here at all, for this is only one of a thousand tickets, the issue of which was so utterly outside the appellant's duty that Dr. Woods intimated to him that in doing so he made himself personally liable. He would state shortly the facts of the case.

Judge FitzGerald—Assuming everything on the face of the process to be true, an action would not lie.

Dr. Andrews—This man was two years, and during that time he issued tickets not by the dozen or by the score, but by hundreds. Well, my lord, the ticket in this particular case was issued requiring the attendance of Dr. Woods on Mrs. M'Grough, and it turned out that he was a person by no means requiring charity. He was in receipt of an adequate salary from the National Board as a national teacher. His wife was the female teacher of the same school, and she, too, was in receipt of a salary which, added to that of her husband, amounted to £70 or £75 a year.

Judge FitzGerald—Would any action lie against the husband?

Dr. Andrews—The duty was imposed on Dr. Woods by the action of the guardian. What he has done has been to impose a duty on the medical officer which he ought not to have imposed, and he ought not to be allowed to take shelter from the consequences of that act behind the provisions of an Act of Parliament. When the matter came before the chairman, the remuneration measured by him was very moderate indeed—in fact, the sum was named by the plaintiff himself.

Mr. Monroe said there was no allegation on the face of the process that any other tickets than this one had been issued by Mr. Crumley. But what the respondent wanted to do was to go into previous occurrences, and to give evidence of other tickets issued by the defendant.

Judge FitzGerald—I will not allow the case to be heard in its present form, but dismiss it without prejudice. The case Dr. Andrews has stated is a most important one, but it should be tried as a case of fraud. I will allow it to be dismissed without prejudice, in order that Dr. Woods may issue a fresh process. The poor-law guardian who conducts himself in the way Dr. Andrews has described is guilty of misdemeanour, and renders himself liable to be prosecuted criminally.

Mr. Porter, Q.C., said it might be that there would have to be some additions made to the process. The facts proved before the chairman had not been brought before his lordship. Mr. Crumley there distinctly stated that he was in the habit of giving out these tickets indiscriminately in the course of his business, and he issued in one year 1,110 tickets.

Mr. Monroe objected. He did not think these statements should go forward to the public if the case was not to be heard. There were members of the press engaged in taking notes of these statements.

Mr. Porter, Q.C.—I don't care about the press. I am stating the facts.

Judge FitzGerald—That is a very small matter in a case of this kind.

Mr. Porter—That there could be no mistake about the matter would be clearly proved. Dr. Woods went several times to Mr. Crumley, and told him he had issued a number of red tickets which he should not have issued. He warned him on several occasions before this, and he called and told him of the meeting, and requested him to attend it, at which he got this very ticket cancelled. But previous to its being cancelled, Dr. Woods had attended on Mrs. M'Grough in her confinement, and made several necessary visits afterwards, he believed ten in all. Mr. Crumley even went so far as to issue red tickets to parties, who previously had gone and employed Dr. Woods, and offered to pay him his fees, and which fees he refused to take, because he could not conscientiously undertake to attend the patient, inasmuch as he was overpowered with overwork. He told this to Mr. Crumley. If every member had issued tickets in the same ratio as Mr. Crumley, Dr. Woods would have had about 38,900 distinct cases to attend to in the year.

Dr. Andrews said he would ask his lordship to amend the process. Mr. Crumley issued this ticket and compelled Dr. Woods, by the issue of it, to attend upon a woman who was not a person entitled to gratuitous attendance within the meaning of the Act. That statement would be supported by evidence, and that being so, the amendment of the process could be no surprise whatever to Mr. Crumley. The fact was, this came out on the evidence in the court below, and Mr. Crumley boldly said he issued the ticket without any hesitation.

Mr. Monroe opposed the application. He said it would be unfair to his client to amend the process, so as to charge him with having fraudulently issued this ticket, and to put him on his defence for issuing certain tickets last year. It would be unfair, having regard to this fact, that Dr. Woods attended Mrs. M'Grough on this ticket, and attended her without objection.

Dr. Porter—Nothing of the kind. He did object.

Mr. Monroe—Pardon me. He attended her without objection till he found that another doctor had been called in. When this case comes to be investigated we will see what the animus of it is.

Judge FitzGerald—The fact is, the issue of tickets in this way would be a very gross fraud. I must say that I am strongly of opinion that any guardian who would issue tickets in this way is not only abusing his authority, but is guilty of a gross and palpable fraud. It is a misdemeanour in law, and renders the guardian who does it liable to a criminal prosecution. I wish to state broadly that an injury might be inflicted on medical gentlemen by such means, and the plaintiff was entitled to join issue against it. Dr. Woods was quite right in instituting this action. He has done a public service by providing for an open investigation. But at present I must dismiss it without prejudice, in order that the case Dr. Woods is about to bring may be properly brought into court. It is an injury to him—it is a fraud; and if it should ever come before me again, I should give the greatest latitude in the investigation of it. It is a gross abuse of authority and a misdemeanour. Dismiss without prejudice and without costs.

Mr. Monroe thought it right to say that if ever that case were attempted to be made, Mr. Crumley was quite prepared to justify what he did.

Counsel for appellant, Mr. Monroe and Mr. Overend, instructed by Mr. J. B. Ross; for respondent, Dr. Andrews, Q.C., and Dr. Porter, Q.C., instructed by Mr. Givan.

◆

WESTPORT DISPENSARY COMMITTEE.

A communication from the Local Government Board was read in reference to the charges against Dr. Johnston. It said, *inter alia*, that on the 11th April, Kane handed Dr. Johnston a red ticket for his attendance on his wife, and that, although he urgently requested Dr. Johnston's immediate attendance, and although the latter promised to comply with his request, he did not visit the case till the next day, when the woman was dead.

Lord John Browne proposed the following resolution, which was unanimously adopted :—

"That, while we cannot altogether acquit Dr. Johnston of blame in the transaction, yet we do not view it in the same serious light as the Local Government Board. It appears that Mrs. Kane was churched, but we have reason to believe that she was not anointed. We believe every word of Dr. Johnston's evidence, and have no doubt that if he had been told or if he had thought that Mrs. Kane's case was a serious one, he would have visited her forthwith. Dr. Johnston has been 14 years dispensary officer of this Union, and we have consequently had the best opportunities of judging of the way in which he performed his duties. We have always found him most careful and attentive, and believe him quite incapable of any wilful neglect. We trust, therefore, that the Local Government Board will be satisfied with the very strong expression they have given of their opinion in this case, which we know Dr. Johnston feels most acutely after his long and faithful service."

At the subsequent meeting of the guardians the following resolution was unanimously adopted :—

"The guardians entirely agree with and concur in the resolution of the Westport Dispensary Committee relative to Dr. Johnston, and think it would be a real misfortune to the district, and much injury to the Union, if he were to resign. They hope, therefore, that the Local Government Board will not press the matter any further."

PRESENTATION OF A TESTIMONIAL TO DR. HAYES, OF SHANAGOLDEN.

(From the *Limerick Chronicle.*)

A LARGE meeting of the friends of Dr. Hayes, lately medical officer of Shanagolden and Ballyhill Dispensary District, was held in the town for the purpose of presenting that gentleman with a testimonial on his departure from amongst them to take up his residence in Rathkeale. Though the hosts of friends he possesses throughout the country felt gratified at Dr. Hayes election as medical officer to the Rathkeale Workhouse and Dispensary, the feeling amongst those of the number resident in Shanagolden was mingled with deep regret that they should have, in consequence of his promotion, lose the advantages of his immediate connection and acquaintance. He endeared himself to all—rich and poor, by professional and other services rendered during his long residence in the district, and they feel they cannot easily be recompensed for his loss. The proceedings at the meeting were of the most unanimous description, and there was only one desire, that the testimonial should be highly worthy the object the committee had in view. The Chairman, in explaining the object of the meeting, said :—"Like all other good intentions, however, our addresses and testimonials are very often ambignous in their nature ; with other joyful expressions are often mingled a great deal that is sorrowful, and these sorrows are multiplied when we discover suddenly that under all our congratulations are hidden deep feelings of regret for loss of a dear friend (hear, hear.) Our sadness comes intensified when we discover one by one that every man amongst us is losing one of the best friends we could have on earth, the guardian of our own lives as well as of our families. Where would the numbers whom Dr. Hayes served now, if he had not rescued them from the iron grasp of death? Who is the man or woman, the priest or man, that can feel unmingled joy at signing an address to Dr. Hayes, when it is one at parting with him (hear, hear.) Mr. T. Hedderman said he thought the first business they had to do to place themselves in proper working order was to appoint officers to carry out the objects of the meeting (hear.) Before proposing a resolution to that effect, he wished to say how entirely they coincided in the observations of their respected and very rev. Chairman. No one who knew Dr. Hayes could have a doubt as to his richly deserving any compliment (applause.) They envied the people amongst whom he was going. They were getting a physician of great worth, and they (the residents of Shanagolden) were losing one in whom they proposed unlimited confidence. He would detain them no longer, but at once propose that Mr. James Nolan, Parkwater, act as Treasurer to the Testimonial Committee, and Mr. James Sheehan as secretary (hear.)

Over £70 was subscribed at the meeting, and it is anticipated the testimonial will be one of the largest ever presented in the country.

◆

MAYO ASSIZES.

Before Mr. JUTICE O'BRIEN.

REMUNERATION OF MEDICAL WITNESSES.

MR. A. B. KELLY applied to the judge to direct the Crown Solicitor to pay Dr. Crean his expenses to and from Wales.

Judge.—You must give him his proper expenses, Mr. Jordan.

Crown Solicitor.—Dr. Crean was bound to prosecute here, my lord ; I gave him his expenses to and from Ballyhaunis.

Mr. Kelly said Dr. Crean was after being married, and was in the middle of his leave, and had to return here from Wales to give evidence.

Crown Solicitor.—He is here now. If he chooses to amuse himself going to Wales I'm not to be following him.

Judge.—He must get his travelling expenses.

Mr. Jordan said he paid him £7 3s.

Judge.—You have to go to Wales, Dr. Crean.

Dr. Crean.—I have, my lord, my wife is there yet.

The Judge directed the Crown Solicitor to pay £4 addittional to Dr. Crean, adding, at the same time, that Mr. Jordan was quite right to be particular, as he (the learned Judge) knew there was a most strict investigation made elsewhere.

The court then adjourned.

◆

CARLOW ASSIZES.

SUPERANNUATION OF INFIRMARY SURGEONS.

MR. FITZMAURICE brought under notice the application for superannuation of Dr. Thomas J. Rawson, Surgeon to the County Infirmary and County Gaol. The existing salary was £183 1s. 10d. per annum, and a medical certificate from Dr. M'Dowell was produced certifying Dr. Rawson's unfitness to continue to perform the duties. The Grand Jury granted superannuation at the rate of £122 1s. 2d. per annum, the office having been held for forty-four years.

◆

PAYMENT OF MEDICAL WITNESSES AT ADJOURNED INQUESTS.

AT the fiating of presentments at the Mayo Assizes last week the Foreman of the Grand Jury said there was a question he would trouble his lordship with. It appears there was an inquest on which it was necessary to have a *post-mortem*. There were two doctors. The *post-mortem* went on till late in the evening, and the inquest was resumed the next day, when the doctors had to attend to give the evidence. The doctors claimed a fee for the next day, and the Grand Jury did not know whether they were entitled to it.

His Lordship said the medical men were entitled to the extra fee. If a witnesses attend here a second day he must be paid, and they should be paid at the inquest as well.

◆

CORRESPONDENCE.

COMPULSORY SUPERANNUATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I beg to endorse the sentiments of "An Old P.L, M.D.," as in your publication of June 20 expressed.

I am one of the same order since 1834, but as God has blessed me with health up to this time of my life (67), I am informed that to resign would be *madness*, as I never would succeed in obtaining superannuation unless *incapacitated* to go elsewheere to practice.

I remain, yours truly,

ONE OF THE OLDEST P.L. DOCTORS.

◆

REPORT OF HEALTH OF DUBLIN AND SUBURBS FOR WEEK ENDING JULY 22, 1876.

Total registered deaths in Dublin and suburbs * ...	119
Ten years average of same week	115
Excess of mortality above average	4
Ratio of deaths, suburb of Rathmines ...	24 per 1,000
" " " Donnybrook †	16·4 "
" " " Blackrock ...	28·9 "
" " " Kingstown ...	28·1 "
" " Entire Dublin district ...	19·7 "
COMPARATIVE RATIOS—London	28 "
" " Glasgow... ...	25 "
" " Edinburgh ...	18 "

---

* District extends over 10,050 acres, and contains 314,666 persons.

† This district includes City of Dublin and Incurable Hospitals.

The deaths from zymotic diseases registered during the week amounted to 19 (the average number for the corresponding week of the previous ten years was 24·9). Of the deaths from zymotic diseases there were but 2 from fever (enteric), 6 were from scarlet fever, 3 from diphtheria, a like number from diarrhœa, and 1 each from quinsy, measles, and whooping-cough.

Seven children died from convulsions.

Twelve deaths were caused by bronchitis, and 2 by pneumonia.

Apoplexy proved fatal in 3 instances, paralysis in 5, heart disease in 9, aneurism in 1, Bright's disease in 1, and liver disease in 3.

Eighteen persons died from phthisis, 4 from hydrocephalus, 3 from mesenteric disease, 6 from cancer, &c.

The deaths from the seven principal zymotic diseases in the entire district equal an annual rate of 2·6 per 1,000 inhabitants, the rate for the city being 2·3 (2·3 in the North City Districts, and 1·9 in the South), and for the suburbs 3·8 per 1,000.

◆

An Electrical Eye.—In 1873, Mr. May, a telegraph clerk employed at the Valentia station of the Atlantic cable line, first observed that the electrical resistance of selenium was instantly altered by light, the resistance being diminished by increase of light.

Dr. Siemens has made use of this peculiarity of selenium in the construction of an artificial eye. An electrical circuit is arranged, of which a bit of selenium forms a part, and constitutes the retina. When a strong light is admitted into the lens and falls upon the selenium retina, the current of electricity flows, and is made to work the artificial lids of the eye, opening or closing them according to the intensity of the light.

ADDRESS IN MEDICINE. (a)

By Edward H. Sieveking, M.D., F.R.C.P.,

Physician Extraordinary to Her Majesty the Queen; Physician in Ordinary to H.R.H. the Prince of Wales; Physician to St. Mary's Hospital, &c.

A certain noble lady was asked by her daughter-in-law for advice as to the best method to be pursued in educating her children. The reply recommended "a little wholesome neglect." This apparently paradoxical suggestion was not intended to imply that her ladyship undervalued systematic training and education, but that she trusted much to the natural tendencies of growth and development to bring out the latent forces, provided they were guided by superior knowledge and intellect into their proper channels. The answer was a protest against pedantry and the procrustean bed of the pedagogue, which in former times, as now, too commonly seeks to establish an uniformity of level and appearance, regardless of the impulses of nature.

A trim garden in the Louis Quatorze style causes us to admire the ingenuity of the gardener, who, by his shears, would compel the bushes and trees to assume any fantastic shapes that his fancy led him to determine upon; but the lover of nature finds in his productions no food for the imagination or for the cravings of the heart, for he feels that the same labour and time bestowed upon developing the glories and harmonies of colour, form, and perspective would have better served to raise him from the mean and grovelling to that which is exalted and eternal.

That which excites the admiration of foreigners in our country and constitution, and runs counter to so many preconceived notions of the fitness of things imbibed by men who have been educated under a different *régime*, lies really in "the little wholesome neglect" that the Briton has enjoyed ever since he has acquired an historical name. He has been allowed to grow, or rather, in spite of frequent attempts to curb and stunt him, he has learned to know his strength and to assert his independence. It is not appropriate that I should, in this place, dwell upon any question of the political development of our country; but the preceding remarks suggest themselves forcibly to anyone who, on an occasion like the present, casts his eyes back upon the features that mark the growth and expansion of the body, an integral part of the commonwealth, to which we, the medical men of Great Britain, belong.

As a profession, we have enjoyed but little of the fostering care of Parliaments, of Corporations, of Universities. What they have done for us has rarely been owing to their spontaneous action, but has been mainly due to that *vis à tergo* which Lord Palmerston, in a different sphere, demanded when any great measure of public utility was urged upon him. Our efforts and success will be none the less if we occasionally, while taking breath in our race, look back to examine our previous course, to know the sloughs in which we have floundered, the pitfalls we have escaped, to obtain a clear view of the goal that shines before us in an ever brightening and broadening light.

A great future lies before us. No utopian vision of fantastic delights, no weird dream of golden joys and boundless felicity, but a prospect that forces upon us the conviction that we are entering upon a field of wider duties, of greater service to our fellow man, of a nearer approach to the fulfilment of our highest destiny as members of a Christian commonwealth.

Many who are now honouring me with their attention may think that so much remains to be done by the profession that they may be disposed to regard lightly the labours and achievements of the past. But those whose memory, like my own, can bring before them the events of the last forty years, and who can realise to themselves the state of the medical profession in our island at the earlier part of the present century, will form a different estimate. Most of the labourers who have brought about what I cannot but call our present hopeful condition have passed away. But it is right and fitting and in accordance with the spirit in which these addresses were originally established that our gratitude, while it is not unmindful of what we owe to our contemporaries, should follow those who have gone before with loving hearts.

(a) Read before the British Medical Association at Sheffield.

At the commencement of the nineteenth century the medical profession was still in a chaotic state in Great Britain and Ireland. Its detractors denied that it occupied a scientific status, and in spite of the eminence of some of the heroes of our calling, we could scarcely ignore the trade-mark which was conspicuous on its documents. In vain have I sought for any evidence of corporate professional feeling in the earlier history of British medicine. Great names—aye, and greater than Italy, Germany, or France can boast of—illumine our roll of distinguished citizens; but how many of them had to lay the foundation or their medical knowledge in foreign schools, because the means were wanting at home to acquire the alphabet of their profession?

Linacre, the founder of the Royal College of Physicians, studied at Bologna and Padua, where he took his degree of Doctor of Medicine; Caius studied physic under Montanus, and dissected with Vesalius, at Padua, where he graduated; Harvey, to whom the whole world bows in reverent admiration, learned his profession under Fabricius ab Aquapendente, Minadous, and Casserius, and took his degree at the same university. Leyden, Heidelberg, Avignon, Paris, Montpelier, are some of the many foreign universities, which, as we learn from Dr. Monk's erudite *Roll of the College of Physicians*, claim as their alumni most of the eminent medical men belonging to the sixteenth, seventeenth, and even far into the eighteenth centuries. These men did not, as is well and wisely done by physicians and surgeons of the present day, go abroad to compare foreign with home experiences, and to perfect a professional education of which the foundation had been laid in their own schools and universities, but they undertook the risk and fatigue of travel, which in their days was no slight matter, to acquire knowledge which was unattainable in their own country.

I have in vain sought for early evidences of medical teaching in England, or especially in the English universities, before the beginning of the sixteenth century. Nicolas, of Farnham, and John, of Gaddesden, who treated Edward III. when he had the small-pox, by wrapping him up in a scarlet cloth, and discovered the method of distilling fresh from salt water, appear to have been the first exceptions to the rule that our princes brought over their medical attendants from abroad. Nicolas de Farnham (as we are told by Matthew, of Paris), (*a*) who was elected in 1241 to the see of Durham, had been rector in arts at Paris, and afterwards practised medicine at Bologna. He became pre-eminently distinguished in, and obtained great favour by, his skill. The king and queen, Henry III. and his consort, by the advice of some learned men, and expressly at the instance of Otto, the legate, the Bishop of Carlisle, and some other of the king's secret advisers, summoned Nicolas to take charge of their souls and bodies, and to be their familiar counsellor, in which office he conducted himself well and prudently till he was elected to the said episcopal dignity.

The first medical lectures of which I can find any record were delivered in Oxford by a foreigner of the name of Andrew Alazard, (*b*) who had graduated at Montpelier, and was appointed by the chancellor and proctors to lecture on medicine, and to explain, from tables of his own, *Avicenna de Pulsibus*.

So little, however, was the science of medicine appreciated in Oxford during the sixteenth century, that the university admitted, about 1550, Simon Ludford, originally a Franciscan Friar, and subsequently an apothecary in London; and afterwards David Langston, a coppersmith, two ignorant, unlettered, and incompetent persons, to the honours of a baccalaureate in medicine. The visitors of the university, on being applied to by the College of Physicians (*Caio Præsidente*), interdicted the university from a repetition of their license, and provided that a certain course of study should be followed by each candidate previously to his incorporation. (*c*) The utter neglect of medicine by the highest educational bodies in the realm was not redeemed by any supplementary efforts on the part of others. The barber-surgeons, who were incorporated by letters patent from Edward IV, in 1461, (*d*) and whose functions were of the most limited nature, were the only representatives of the general practitioner of the present day, until the corporation of barber-surgeons was dissolved in the 18th of George II. At this date, the surgeons, who seceded from the barbers, were incorporated, but they were not endowed with a charter till the beginning of the present century. The apothecaries, as a mere trading company, were founded, in 1606, by James I., but they exercised no influence on the profession of medicine till Parliament, in 1815, conferred upon them powers which they have since wisely exercised and developed.

Valuable as have been the services of the College of Physicians in giving a local habitation and a name to medicine, and in holding a royal ægis over many great men of science, neither this corporation, nor the barber-surgeons, nor, at a later period, the College of Surgeons, could be regarded as representing or acting with the body of medical practitioners, or as aiding the social or scientific status of the great body of the sons of Æsculapius in England, whose numbers were gradually swelling into many legions. The College of Physicians—may a devoted son be permitted to say as much without an approach to disrespect—failed to recognise the grand opportunity offered to them in the early part of the present century, of taking the entire management and discipline of the medical profession into their own hands, and the consequence was, that a City company bravely came to the rescue. All honour to the Hall in Blackfriars! The master and wardens of the Apothecaries' Company rose to the dignity of the occasion; and what they have done, since 1815, for the promotion of the best interests of the medical profession, deserves not only a bare allusion, but our most cordial acknowledgments.

But jealousies and bickerings continued, and the different branches of a great profession could not even now claim any of the various institutions existing throughout the country as representing their first interests. The clouds surrounded us more and more, and appeared increasingly gloomy, when an acute observer might observe a silver streak in the west, heralding the dawn of a brighter era. The dawn of a new life was seen over Worcester—a life which *we* are beginning to realise in all its capacities, and of which meetings like the present are the partial fulfilment of early promise.

Among the many events which, in the recent development of our profession, appear to me to be most characteristic, both from their mode of origin and the significance of their bearing upon the spirit of the times, as upon the future of our corporate and scientific growth, there are especially three, to which I would crave your present attention, in order that, on the one hand, we may recognise the deep obligations which we owe to our predecessors; that, on the other, we may seek to derive from past experience the lessons that should guide us and our successors in our future career. The three events to which my introductory remarks may have already turned your thoughts have especial reference to what appear to me the chief phases of our advancement as the followers of a beneficent and learned calling, viz., our relations to each other and the State; our relations to the science of medicine; and our relations to education.

The *first event* was inaugurated on the 17th of July, 1832, when Dr. Hastings induced fifty gentlemen of the medical profession to assemble, under the presidency of Dr. Johnstone, of Birmingham, in the board-room of the Worcester Infirmary. On that occasion, Dr. Hastings delivered an address which was pregnant with all the great consequences to which the Provincial Medical and Surgical Association has since led. Allow me to recall his own words, as published afterwards in the first volume of the *Transactions* of the Association, which appeared in 1833. "I congratulate you, gentlemen," he said, "that the day for forming a Provincial Medical and Surgical Association has at length arrived—an association which, I trust, is destined to exercise no inconsiderable influence on the future of medical science. Feeling, as I have done, the disadvantages under which the prosecutors of medicine resident in English provincial towns have laboured, in consequence of the want of any system of cooperation, by which their separate exertions for the promotion of our knowledge of the healing art may be so united as to render them more influential and more extensively useful, I cannot but hail the day—*hunc lætum medicis diem*—as one of peculiar promise, as one likely to lead to the most important results."

You, gentlemen, know as well, and better than I do, how far these prognostications have been realised. Three hundred

members at once rallied round Dr. Hastings; and the best proof that he had only become the happy expositor of a widespread feeling of the necessity of harmonious co-operation for great common ends, has been afforded by the progressive adhesion of medical men from all parts of the country to the programme he laid down. Very valuable contributions to literature (medical, surgical, hygienic, biographical) appeared, first in the *Transactions*, and subsequently, in 1840, in the *Provincial Medical and Surgical Journal*, edited for the Association by Drs. Hennis Green and Streeter. In the meantime, the interest in the Association had spread to the metropolis, and the particularism, to use a favourite continental term, which very properly belonged to the Association at its outset, was abandoned; the jealousy between the provinces and London yielded to the imperative feeling of brotherhood which unites us all; and, in 1853, according to a resolution adopted at the meeting held in Oxford in the previous July, the *Provincial Medical and Surgical Journal* appeared, under the editorship of Dr. (now Sir John) Cormack, as the *Association Medical Journal*. This was now placed in the hands of the subscribers every week, instead of, as previously, once a fortnight. The change was effected, not without some opposition on the part of those who, fearing too radical changes, doubted the soundness of the Oxford decision; but, as the editor observes, in his opening remarks to the new series, it was a "strong declaration of the necessity which the progress of events has imposed on the Association of pursuing that line of duty which had hitherto been acted upon with that augmented vigour which a wider sphere of action required—a vigour which could only be effectively developed by greater frequency of publication, and by the possession of a literary and scientific centre in London, where editorial resources are more abundant, more varied, and more easily available than in any other city in the world."

From that time, the arterial pulses that beat throughout the kingdom acted synchronously and rhythmically with the heart; a sympathetic centre had been found, which tranquillised or warded off local disturbances in the circulation; and our body politic insured a renewal of life, which

"Broadening down from precedent to precedent,"

promised, as it still promises, ever richer and more abundant fruit. There may and must be differences of opinion as to many of the questions that have agitated the Association during the last twenty-three years, and will continue to do so, unless the worst of all events—stagnation—were to ensue; but whatever the shortcomings may be that can fairly be laid to our charge, I question whether any profession has ever done more in so brief a space of time to regenerate itself, to show a more healthful activity, or to produce more beneficial and enduring results. Those results, whether we refer to the expansion, the increased and unselfish energy of our corporations, to the Act of 1858, with the consequent formation of the Medical Council, the publication of a national *Pharmacopœia*, and the recognition of State Medicine, to speak only of a few salient features, take their root essentially in our Association. Their very mention refutes the accusation which has been heard from time to time, that medical men showed some of the worst features of trades-unionism. The great leaders to whom we have given our willing adhesion have universally looked to the improved education of the profession, the diffusion of its benefits among our countrymen, the prevention of disease, and the physical and moral advancement of the nation, as their guiding principles. They have put a Christian interpretation upon the Hippocratic oath, and have not hesitated to make personal and corporate sacrifices where the good of the community appeared to demand them. There has even been a tendency to self-depreciation occasionally, which was not justified by the circumstances, nor was it compatible with that healthy frame of mind which should urge on to higher achievements. But those who have a personal experience of things as they were thirty years ago can scarcely hesitate to admit that, in all aspects in which our profession can be regarded in relation to our fellow-citizens, it occupies a better position now than then. Much has been said about our political status. I am not one of those who consider Parliamentary honours undesirable for members of the medical profession who possess a patrimony sufficient to enable them to disregard the emoluments of practice, or who have realised a competency by the ordinary routine; but, while circumstances are never likely to allow their number to be very large, I hold that, speaking broadly, the political arena, in its usual limited sense, is not the one for which our education or our sympathies generally most fit us. The medical man is so trained to look at and examine the questions that present themselves to him in all its aspects, that he can scarcely make a good party man. Besides, we are exempt from serving on juries, and from filling many of those useful and honourable civic posts which help to educate the rising politician. We give much unpaid or underpaid work of another kind, as our quota to the treasury of the commonwealth; and the time may come—nay, I would trust that it is not far distant—when some of the most distinguished, zealous, and far-sighted of our brethren may be called to a higher position in our Sovereign's councils than has yet been the case, not for the mere vulgar gratification of a personal ambition, but because there are many questions that come more and more into the foreground, upon which it is desirable that individuals who have received that medical training which can alone qualify them to advise, should publicly exercise a power and a responsibility which shall develope, extend, and strengthen the health of the nation.

Those who are prejudiced against the view that medical men have a capacity for becoming "rulers of men" have only to look to our vast colonial possessions to learn that the training of the physician qualifies him for posts of the highest and most responsible character. Can we believe that in crossing the Atlantic, the Pacific, or the Indian Oceans, a transmutation takes place of a baser to a nobler metal, and that a man who can worthily rise to the highest places in other hemispheres is incompetent to give wise counsel and to carry strong and benificent measures while he is in contact with his native soil?

It is not without significance as to the influence which the question as to the nation's health is exerting upon the public mind when we find a Prime Minister putting hygiene and its bloodless victories on a level with the sanguinary achievements of generals and admirals. Mr. Disraeli, (*a*) on the 9th of November, 1875, said: "I believe that a policy that diminishes the death-rate of a great nation is a feat as considerable as any of those decisive battles of the world that generally decide nothing." Whatever our politics, it appears that here we have the indications of a policy upon which "Whig and Tory all agree," but it is the first time that the principle underlying it has been announced as guiding the action of a First Lord of the Treasury. We draw a good augury from it. Echoing his leader's sentiments, Mr. Cross, on the same occasion, dwelt upon the duties devolving upon the City authorities, "to rid the City of all those plague-spots which have spread disease and misery throughout the whole metropolis," and he told them that their powers, "rightly employed, would be the means of conferring a great benefit upon the community at large." Post-prandial effusions may not have all the dignity of official statements; still, assuming that the proverb *In vino veritas* applies to ministers not less than to ordinary mortals, we may indulge in the hope that, although the speakers might be unwilling to carry out their argument to its legitimate conclusions, they recognise the great principle for which we are contending.

In small and scattered communities the want of sanitary supervision does not immediately make itself felt, though, with our present knowledge, it is manifest that legislators greviously neglect their duty if they do not, in the infancy of townships and states, take those steps which shall render it unnecessary, with their growth, to regret early *laches*. With our present and increasing population, with all the peculiar demands made upon every fibre of the individual, it is especially the duty of governments to see that labour and life be economised, which means that health be made a State question.

Whether it would be wise to seek the establishment of a distinct ministry of health and medicine; whether we should try to secure for the best men among us seats on Her Majesty's Privy Council; or under what other form the medical interests of the country could be best administered, it would be out of place to discuss here. The members of the Association have better opportunities of ventilating such details. But of this I feel assured, that the time will soon be at hand when, in some way or other, greater power must be put into the hands of physicians in order to secure the most perfect development of hygienic measures for our country. (*b*)

(*a*) See *Times*' report of the Lord Mayor's banquet at Guildhall.

(*b*) Since these remarks were penned Mr. Gladstone, in an address of great eloquence, delivered at the London Hospital Medical School, has dwelt on the same topic, and has drawn attention

I conceive that I should have neglected a duty which this occasion imposes upon me had I failed to indicate one, if not the main direction which our associate labours should continue to take. The coryphæi of medicine in all times have had vague presentiments on this subject, but from the celebrated work *On Airs, Waters, and Places*, which Hippocrates published about 400 years before Christ, (*a*) to there markable and interesting volume *On the Civilisation of England*, which appeared two thousand two hundred and fifty-seven years later, (*b*) mankind and their growth are represented rather as the creatures than the controllers of circumstance; whereas I hold that it is our duty to rise superior to the physical world, so that we may compel it to obey us. If we are to subdue the earth and have dominion over it, we must first seek thoroughly to acquaint ourselves with those supreme laws under which the Creator has placed us; bet the very essence of all science, civilisation, and medical power, runs counter to those fatalistic views which the weakness of human nature has so often made paramount; and which, out of harmony with all intellectual and spiritual progress, constitute man the torpid and abject slave, rather than the loving and obedient child, anxious to realise the high destiny to which he is called in this and other worlds.

The members of the Association have ever shown that they took large views of the duties of medicine in regard to man in his relations to nature. The very first volume of *Transactions*, published under the auspices of Dr. Hastings, contains no less than three valuable articles on medical topography: the first, on the furthest south-western extremity of Britain, by Dr. Forbes; the second, on Bristol, by Drs. Carrick and Symonds; the third, by Dr. Kenrick, on Stourport. Willingly would I dwell upon these, and many other similar productions by their successors in the same field; no less than upon the numerous evidences I might lay before you of the influence exercised by the Association upon the development of medicine in the various directions to which I have alluded; this would be impossible within the limits assigned to me. I may, however, be permitted to avail myself of this opportunity of inquiring whether the members of our Association have continued to take that interest in medical topography which appears especially to have attracted its earlier members. We may hope for valuable information on the subject in connection with the locality in which we have to-day met, and with the extraordinary development of certain branches of manufacture for which Sheffield is famous. I would suggest that medical topography, comprising, as it does, the geology, water supply, temperature, and sanitary statistics of a district, is especially a subject worthy of our annual meetings. The researches that it involves demand much labour, probably more directly useful to the community than to the inquirer who undertakes it; and I venture to ask whether it might not well constitute a subject to which every year a portion of our available balance might be allotted for the remuneration of an acknowledged worker in this branch of science. We should thus gradually accumulate a valuable amount of information, which would serve as a beacon and a guide for future inquirers. Could not the Council of the Association be empowered to select one or more members residing in the town where each successive annual meeting is to be held, to devote themselves specially to this work, and to present their report at the meeting? It appears to me that the duties we owe to one another and the State would here find a fitting expression, while, at the same time, we should be attending to the call of medical science, our relations to which embrace the second topic, to which in my opening remarks I invited your attention.

Allow me to advert again to a fact which not unfittingly connects these two branches of my inquiry. It is that medical topography first enlisted the interest and established the reputation of a name whose bearer afterwards did more for the advancement of scientific medicine in this country, and towards securing its recognition at home and abroad, than any other of the great men who have belonged to our ranks. I allude to one, now no more—unselfish, honest, brave, a Bayard of medicine, "*sans peur et sans reproche*"—the author of the first article on medical topography in the first volume of the *Transactions* of the Association—Dr. (afterwards Sir John) Forbes. Would that he were still amongst us, to see that his labours and his sacrifices were not wasted! Having won his spurs in the literary field which the Association opened for him, Forbes commenced his career as a provincial physician; he terminated it as a regenerator of medical science, and may almost be said to have succumbed after a great and abiding victory, as a martyr to the truth which he loved above all things.

(*To be continued.*)

MARION SIMS ON MEDICAL ETHICS AND ANTI-VENEREAL LEGISLATION.

At the opening meeting of the American Medical Association, Dr. Marion Sims, in his capacity of President, delivered at Philadelphia an address remarkable for the bold expression of views which were not palatable to a large and most influential class of his hearers. He dealt principally with the questions of medical education, the code of medical ethics, and the necessity for firm control over the propagation of venereal. On the medical education question he said:—

While medical colleges are so easily multiplied, and while they are mere private corporations, running in competition with each other, we have nothing to hope in the way of reform from them. That first, second, and third course students, if there are any such, should sit on the same benches at the same time, and hear the same lectures year after year, is an absurdity that exists only in our own country, and here it has existed for a whole century without any change or modification. But it cannot go on so for another century.

Already Chicago and Boston take the lead and inaugurate the true scholastic method of classes, and terms of study, and courses of practical instruction, now fully appreciated by such young men as are in earnest in acquiring a thorough medical training.

The Harvard method, with a salaried Faculty wholly independent of fees from students, is the only plan by which we can ever hope for a medical degree of any real value.

In reference to the code of ethics he proceeded:—

We boast of a code of ethics, the best ever given for the government of medical men; and we urge it as a model to be adopted by the profession in other countries. I would not shock the moral sense of this august body by speaking of it in irreverent tones; for I know that there are many, indeed a large majority of this association, who believe it to be as perfect as the Decalogue, and as incapable of improvement. It is looked upon by some of its high priests as the holy of holies, and not to be desecrated by the touch of vulgar hands. It is only by observing the practical operation of laws that we can judge of their fitness and usefulness. Let us measure our code by this universal standard.

Twenty years ago it was considered disreputable for a physician to put on his door, or in his window, a plate giving his office hours. Now every one does it, greatly to the convenience of both physician and public. A few years ago a physician in a neighbouring city was expelled from a society for inserting his name in the general "Directory," with the announcement of his specialty and

---

to the increasing importance of medicine and the medical profession. "That profession," he said, "presented a future of the highest interest. There was in that future the probability that it would gain increased influence—greater as compared with other professions."—(See *Times*, Friday July 14, 1876.)

(*a*) Hippocrates is supposed to have been born in 460 before Christ. It is scarcely a poetical licence to assume that this work was composed when he was sixty years of age.

(*b*) Mr. Buckle's work appeared in 1857.

his office hours. In France they do things differently. There a doctor cannot put his name on the door of his apartment; but he can advertise himself in the "Directory" as broadly as he pleases. Usage makes what is right in one country wrong in the other.

A gentleman high in the ranks of the profession, holding a distinguished position among us, wishing to change his place of residence, writes to me to know how he can notify the world of his intention without violating the code of ethics; and he, and a friend of his, a well-known stickler for the inviolability of the code, hold grave consultations over the easiest way of getting round its provisions without a flagrant violation of them. These are honest and honourable men, and would not wilfully do anything wrong. But they feel that they are hampered by rules that are unjust and oppressive. Pardon me if I ask you, "Is the code of ethics up to the requirements of the times when it compels honourable men to do dishonourable things to promote an honest action?"

Under our code all consultations are secret and confidential, and the friends of the patient are never to know that there was a difference of opinion between the consultants. But was there ever a difference of opinion on such occasions that it did not leak out, sooner or later?

It is derogatory to professional character for a physician to take out a patent for a surgical instrument, or any other invention. A distinguished physician invents a galvanic cautery. He has spent much time and a large amount of money in perfecting his apparatus. According to our code, he cannot, he dare not, take out a patent for it, as any other honest man could do, simply because he is a practising physician. But why should not the physician reap the reward due to talent and inventive genius as well as any other man? Does the profession at large, or does the public, derive any benefit by this robbery of the inventor? None whatever. We simply compel him to give his invention, his time and labour, to enrich the instrument maker. A few brave men, daring to assert their inalienable rights, would establish a precedent that would soon become a law, rendering this clause of the code, as in other instances, a dead letter.

Who among us is ignorant of the value of Dieulafoy's aspirator? A young man, not over thirty, he had the courage to patent his invention. The profession in France at first turned the cold shoulder to him, and said it was a pity that such a talented young man should have made such a mistake as to patent his invention! But now he is called in consultation with leading men in the profession; and the younger members of this association will live to see him a member of the Academy of Medicine, in spite of his patent.

A gentleman in a neighbouring state invents a pessary of great value. He has spent fifteen years in working it out. He has spent a large amount of money in perfecting it. He is poor and in bad health from a dissection wound received five years ago. He writes to me to ask what he is to do to reap some reward for his time and labour. We say, by our code, that he must make a gift of his invention to the profession. But he can only give it to the instrument-maker, and not to the profession. His only course is to quit the ranks of a liberal profession, and enter those of honest manufacturers, and then supply us with his instruments from his own factory. Out of the profession, he is out of its jurisdiction.

The code of ethics is violated every day, either wilfully or ignorantly, not only by the rank and file, but by men high in the profession, men who are considered leaders, advanced thinkers, and workers.

How many of you prescribe chlorodyne, which is almost a specific in choleroid affections? and yet it is a secret remedy. Who among you has never prescribed McMunn's elixir of opium? It too is a secret remedy. Even Henry's calcined magnesia is made by a secret process. The tolu anodyne is daily prescribed in New York and New England by hundreds of leading physicians, and it is but another name for a preparation of cannabis indica. The prescription of all such remedies is a flagrant violation of our code of ethics. But we seem to condone the act, because usage and interest justify it.

There is not a man within the sound of my voice who cannot call to mind some violation of the letter or spirit of the code of ethics, that has occurred under his own immediate observation. Indeed, when we speak of violating the spirit of the code, we may all as one man cry out, "He that is without sin among you, let him first cast a stone."

Several medical gentlemen, notably in New York, Philadelphia, Baltimore, and elsewhere, have lately rendered the greatest service to the profession and to humanity by furnishing us with animal vaccine virus. As they are engaged in a commercial speculation in the virus, and as they resort to conspicuous advertisements of it, they are plainly acting in opposition to both the letter and the spirit of our code of ethics. But where is the man among us who is such an idiot, so dead to all sense of honour and right, as to charge these noble philanthropists with base purposes?

But there is another stand-point from which to view our code. Did it ever occur to any of you that it is capable of being used as an engine of torture and oppression?—that men jealously, maliciously, intent upon persecuting a fellow member, may distort the meaning of the code to suit their malign purposes, thus entering into a regular conspiracy to blacken character, and that under the sanctity of the code's provisions?

Illustrations of this are not wanting, and I could give you some astounding details. But in mercy to you, and in pity for the poor poltroons who, in the name of virtue, could so prostitute themselves to vicious acts, I spare you the recital. I have said, perhaps, too much on this theme; certainly enough to put you to thinking. This is the first time that the validity, the constitutionality, of the code has been openly called in question. But every thinking man here, with a particle of self-respect and self-reliance, has at times felt an inward protest against its unequal operation. I do not ask you to appoint a committee on the code. Let it stand as it is. Honourable men do not need its protection. Dishonest men are not influenced by its edicts. We must educate the profession up to the recognition of a higher law, the unwritten code regulating intercourse between gentlemen. This is the code that governs in England and France. The man that violates it is by common consent dropped out, ignored, and allowed to vegetate in isolation.

As to the suppression of the dissemination of syphilis, Dr. Sims said:—

> Indulge me then for a short time, while I say a few words on this subject—words addressed nominally to you, but really intended for those behind and around you, who live in darkness and utter ignorance of the dangers that threaten them.
>
> So far as the well-being of the human race is concerned, I look upon the subject of syphilis as the great question of the day. It was formerly a question of treatment, of mercury or no mercury. But that time has passed, and now it is a question of prevention, of eradication, of the protection of the well against the contamination of the sick.
>
> If yellow fever threatens to invade our precincts we take steps to arrest its progress at once. If cholera sounds the alarm we immediately prepare to defend ourselves against its ravages. If small-pox infests our borders we circumvent and extinguish it. But a greater scourge than yellow fever, and cholera, and small-pox combined is quietly installed in our midst, sapping the foundations of society, poisoning the sources of life, rendering existence miserable and deteriorating the whole human family.
>
> Does anyone for a moment think I exaggerate the evil consequences of this dread disease? To the medical profession the truth, as I state it, is well known; but as I said before, the public at large are ignorant on this subject, and it is our duty to enlighten them, to point out the

danger, to show the means of protection, and to lead the way of escape.

The facility with which syphilis is communicated is marvellous. It is often given in a kiss. French medical literature teems with examples of this sort. Prof. Gross has seen many such cases. He saw a young lady who had a hard chancre on the lip contracted by kissing. In a few weeks her blood was completely poisoned; subsequently she married, and in due time she gave birth to a child that died in eight weeks covered with syphilitic sores on the vulva and nates.

Prof. Gross also tells us that an "endemic of syphilis occurred in Brives, a little town in France, in 1873, fifteen women, nine children, and ten men having been affected in rapid succession. Great excitement for a time prevailed, wife accusing husband, and husband wife, of conjugal infidelity, when it was at length ascertained that the cause of all the trouble was a midwife, who had a chancre upon one of her fingers, contracted in the exercise of her profession, and who had thus carried the poison from house to house."

A short time ago a healthy-looking man obtained a situation in a glass factory in the north of France. A few weeks asterwards a dozen or more of the glass-blowers had syphilis in some form or other, and were unable to tell how they got it. But the attending physician soon traced the disease to the new-comer, who was found to have a syphilitic ulcer in his mouth, and the others were inoculated by using the same blower that he did.

I have known two medical men infected with this disease by patients while in the discharge of their professional duties. Each had a slight scratch or abrasion of skin on the fingers, and by this channel the poison was carried into the blood. One of them died most horribly in a madhouse from disease of the meninges of the brain, induced by this accidental syphilization; while the other is still eking out a miserable existence, his whole system being pervaded by the deadly poison. Nurses are frequently infected by children born of parents one of whom (always the father) has had syphilis: and diseased nurses often infect innocent sucking babes born of perfectly healthy parents. I have known a drunken vagabond husband to contract syphilis in a low brothel and communicate it to his wife, who unwittingly gave it to her four children, simply by using the same towels and wash-bowels.

The nature of the disease, and the manner of its propagation, were not recognised till eruptions and putrid sores, and ulcerated throats, and agonising pains, and blindness in two of the children indicated too plainly the unmistakable character of the disease.

Some years ago a handsome, dashing young fellow captivated the heart of a beautiful and accomplished young girl, the daughter of one of our wealthy merchants, The sensible father opposed the marriage, but the foolish girl would have her own way and they were married. While on their bridal tour this innocent girl and confiding wife, not seventeen years old, was syphilised by her husband, and her blood was soon poisoned. In due time she became a mother. One of her children had syphilitic eruptions, one lost the bones of the nose, and two others were variously affected with symptoms of a loathsome disease that circulates in their blood, and which will lay the foundation of disease in their offspring, if they should live to have any.

I have seen a cook and a chambermaid with syphilitic ulcers on the fingers. Think for a moment of the danger to innocent people from such a disgusting thing.

Give me a moment to inquire into the relative frequency of this disease in localities where registration brings out reliable statistics.

In the out-patient department of Guy's Hospital 25,800 cases of venereal disease are annually registered in that one institution, being 43 per cent. of the total number of out-patients registered; in the Hospital for Diseases of the Skin, 10 per cent.; in the Throat Hospital, 15½ per cent.; in Moorfields Hospital for Diseases of the Eye, 20 per cent.; in the Workhouse Infirmary, 10 per cent. Among the poor in London applying for relief at the hospitals there are upwards of one hundred thousand annually affected with syphilis in some of its forms.

And from recent developments it appears that San Francisco is worse off than we are. In an able speech delivered by Senator Sargent, in the United States Senate, on the 1st of May, on the existing treaty between China and this country, he brings forward testimony to show that of the hundred and fifty thousand Chinese on the Pacific slope there are not a hundred families, and that ninety-nine hundredths of the Chinese women imported into California are sold and held as slaves—slaves to be used wholly and solely for the purpose of prostitution, and that their presence necessarily breeds moral and physical pestilence.

According to the evidence of Dr. Toland, even boys eight and ten years old have been syphilized by these degraded wretches, who are allowed to openly solicit in the streets, tempting old and young alike.

Shall it be said that we, the representatives of the medical profession of a great nation, the custodians of the health of forty millions of people, cognisant of all these facts, will longer let the people remain in ignorance of the dangers that surround them? No, my friends! We must be up and doing. We must follow in the footsteps of our illustrious leader, Prof. Gross. We must sound the alarm. We must no longer whisper, but we must boldly proclaim the truth, and scatter it broadcast over the length and breadth of the land. We must call to our aid the press, the pulpit, yea, the women of the country. To do all this, we must show the world that we are in earnest.

I have not time to speak of what has been done in France and England for the prevention of the spread of syphilis. Suffice it to say that the plan adopted there is not the one for us. We want no legislation that looks to licensing prostitution, as in France, and we want no partial legislation, as we find in the "Contagious Diseases Act" of England. We would not outrage religious sentiment by adopting a system of fostering vice; nor should we subject the hardy soldier, even for his own good, to invidious restrictions not imposed upon others in the community. Besides, how absurd would the English system work with us, when we have but a nominal army, and that scattered over the frontier, away from the pale of civilisation and its worst vices? Class legislation in any shape and for any purpose is distasteful to the people of any country, and especially of ours.

To protect the public against its ravages, we must strike at the root of the evil. We must seek it out in its hot-beds, and circumvent it with such regulations as to prevent its transmission. We must ask for such laws as will confer upon us the power of dealing with this disease which we already possess with regard to cholera and small-pox.

The carriers of trade between nations, and between great commercial centres in the same nation, are the carriers of syphilis. Syphilis is carried from city to city by men, and women scatter it far and wide in communites. One man may inoculate a half dozen women during the few days his ship lies in port, and these half dozen degraded women may transmit the disease not only to scores of men, but hundreds and thousands may trace their ruined health, directly or indirectly, back to the half dozen women who were infected by one man. We must then manage to get the control of the men who are likely to import the poison, and we must get equal control over the women who will assuredly disseminate it through the community. How is this to be done? is a question that has been asked over and over again, but never answered to the satisfaction of both religionists and philanthropists.

There can be no difference of opinion among us regarding the two following propositions:—

1st. We want a system of sanitary inspection and control that will enable us to prevent the importation of syphilis from abroad.

2nd. We want a system of sanitary inspection and control that will enable us to take charge of the subjects of syphilis at home, and prevent them from spreading it through the community.

Now what I propose in regard to syphilis is simply to give to the already existing Boards of Health in the various cities the same power over syphilis that they now possess over cholera, small-pox, and yellow fever. They now have the power of ferreting out small-pox, and of sending it to hospitals for treatment; and they should have the same power of searching out the abodes of syphilis, and of sending its victims to hospitals for treatment.

On all steamers or sailing vessels, whether foreign or coastwise, entering port, the surgeon of the vessel should be required to make affidavit that he had examined personally every seaman, and every male steerage passenger on the day preceding their arrival in port, and that there was no case of cholera, small-pox, yellow fever, syphilis, scarlatina, or other infectious diseases aboard. If there should be syphilis, then the subjects of it should be taken in charge by the Board of Health, and sent to hospital for treatment, to be retained there till cured, or to be returned to the vessel from which they were taken, whenever said vessel should be ready to sail from port again.

For stamping out the disease in towns and cities, their Boards of Health must have plenary powers of an absolute character over syphilis, not more so, however, than they now possess over small-pox.

Thus you see that I would simply include syphilis in the great family of contagious or communicable diseases, and make it subject to the same laws and regulations that we already possess for their management.

Do this, and we cannot be accused of licensing vice, or of fostering adulterous intercourse. In cholera and yellow fever, and in small-pox and syphilis, we recognise cruel and fatal diseases easily communicable, each attacking the human family in its own peculiar deadly way; and we propose to deal with them all in the same manner, taking the surest, safest, and quickest method of protecting the community against their pestiferous presence, and of preventing their spread among the well.

◆

A COURSE OF PAPERS ON THERAPEUTICS: INCLUDING THE PHYSIOLOGICAL ACTION OF MEDICINES.

By W. Handsel Griffiths.

(Continued from page 87.)

ACIDUM HYDROCYANICUM.

Locally applied, prussic acid rapidly destroys muscular irritability. It seems to produce a topical anæsthetic effect without influencing the nerve-centres, and if sufficiently concentrated it paralyses the peripheral sensitive nerves. Robiquito's fingers became numb in consequence of their exposure for some time to the vapour of this acid. In itching cutaneous affections it is a useful application particularly, according to Dr. Thomson, in those of an impetiginous character. That physician uses a lotion consisting of a drachm and a-half of the acid to eight ounces of water. Glycerine is a good vehicle for the external administration of prussic acid, and as an ointment, from half a drachm to a drachm of it may be mixed with unguentum zinci. The application of hydrocyanic acid in cutaneous affections of the genital organs is recommended by Schneider, of Dusseldorf, but the writer would earnestly caution his readers against such a treatment, for as prussic acid may exert a deleterious action even through a sound cuticle, it would be far more likely to do so if it were brought into contact with a mucous membrane. Whenever resorting to the external application of hydrocyanic acid care should be taken that the skin be not abraded.

Prussic acid was first introduced into England by Dr. Elliotson for the cure of gastralgia. We have the testimony of Bailey, Elliotson, Pereira, Thomson, and others as to the efficacy of this agent in those cases in which the prominent symptoms are epigastric tenderness, indigestion, flatulence and palpitation of the heart. Pereira remarks, however, that it either effects a perfect cure or proves a complete failure. In enterodynia, colica pictonum, and in other painful affections, as in chronic ulcer, cancer of the stomach &c., prussic acid has been found to afford relief. In a severe case of spasmodic dysphagia, Richter obtained a rapid cure with prussic acid in conjunction with counter-irritation of the neck. One of the most useful attributes of hydrocyanic acid is its power of allaying vomiting; Pereira says that he has seen it cure the vomiting of English cholera when opium has failed. In the irritable stomach of pregnancy and in sea-sickness prussic acid acts beneficially. It has been said to prove serviceable in checking the diarrhœa of phthisis. In some forms of dyspepsia, prussic acid in combination with bicarbonate of soda and peppermint water is a favourite remedy.

Veitz first, and subsequently many other observers, including Claude Bernard, found that in animals dying suddenly from prussic acid poisoning, the blood in the veins and right side of the heart is of a bright red colour. On the other hand, Bischoff and other equally accurate investigators state that venous blood alone is to be found in the bodies of animals poisoned with prussic acid. It was reserved for Preyer to reconcile these discrepant statements. He found that the first effect of the acid is to change even the venous blood to a bright arterial scarlet, but that after a time the blood even in the arteries assumes a dark blue colouration. The first effect of hydrocyanic acid on the blood therefore is to cause excessive arterialisation, and this is followed by excessive carbonisation. Preyer proved by the spectroscope that in the latter stage the blood is almost wholly free from oxygen. Various theories have been advanced to account for these blood changes. Hoppe-Seyler suggests that the first action of the poison on the blood is to deprive the red globules of their power of yielding up oxygen in the capillaries, but the weight of evidence is altogether opposed to this assumption. Gaethgens has shown that in the first stage of prussic acid poisoning less than the normal amount of carbonic acid and of exhaled oxygen is eliminated, the latter result being probably due to lessened inhalation of oxygen. That the lessened excretion of carbonic acid is not due to the same cause is shown by the fact that the percentage of carbonic acid in the expired air is less than normal, while that of oxygen *is* normal. There can be little doubt that during the first stage of prussic acid poisoning oxidation is arrested, but the precise mode by which this result is effected is as yet a matter of conjecture. Alteration in the form of the corpuscles has been suggested as the cause of the change of colour in the blood, but although prussic acid does undoubtedly affect the form of the corpuscles in drawn blood, it has no effect on the corpuscles of circulating blood, for after death from prussic acid the globules are found unaltered in shape.

Prussic acid passes speedily into the blood, and is as speedily eliminated, probably with the breath; if after a poisonous dose, therefore, life can be supported for half-an hour, the patient is generally safe.

Wahl found that under the influence of prussic acid the blood-pressure rises. Prussic acid acts directly on the heart-muscle or its ganglia, producing diastolic arrest if given in sufficient doses; small doses simply show the heart's action. It has been recommended as an arterial sedative, but we have many other infinitely less objectionable and more efficacious remedies of this class. Andral and Becquerel regard prussic acid as being positively injurious in heart diseases, but without doubt it does good in functional palpitation. Dr. Hope recommends it as a palliative in hypertrophy, and it has also been employed to allay the distressing symptoms of aortic aneurism.

Prussic acid in all doses lessens the respirations. From experimental observations it is deduced that it exerts some direct action on the centres of respiration in the medulla oblongata; it may also be, as suggested by Preyer, that its prime respiratory action is on the peripheral ends of the vagi.

Prussic acid has been highly extolled as a remedy in whooping-cough, and Dr. E. P. Atlee states that he has effected a cure with it in over 200 cases in from four to ten days, or at furthest within a fortnight. According to the experience of Hayward, Richter, and others, it is chiefly useful in the latter stages of this affection. Dr. West finds that it acts most beneficially in cases in which the paroxysmal character is well marked. Unquestionably in some cases it acts with marvellous efficacy, whilst in others it appears to act injuriously. The writer is therefore driven to the conclusion that there is some, as yet, unknown condition which regulates the efficacy of prussic acid in whooping-cough. The following is Dr. West's formula:—

℞ Acid hydrocyanici, ♏iv.;
Sodæ carb., gr. x.
Mist amygdalæ, ℥j. M.

A teaspoonful every sixth hour for a child nine months old. We may here mention that the administration of prussic acid to young children calls for the greatest caution.

It is widely admitted that in simple nervous cough independent of any pulmonary affection, no other medicine is superior to hydrocyanic acid. In chronic lung diseases and in phthisis prussic acid may be useful in allaying cough, but in other respects it must be regarded as by no means possessing the curative powers attributed to it by Brugnatelli, Granville, Magendie, and others. It was at one time regarded as a specific for acute inflammation of the lungs, an opinion held by few therapeutists of the present day. In laryngismus stridulus prussic acid has been employed advantageously by Dr. Reid, and Dr. Thompson regards it as almost a specific in phthisis trachialis. Many writers approve of it as a remedy in spasmodic asthma and also in angina pectoris.

The action of hydrocyanic acid on the nervous system is direct, and is not preceded by primary stimulation. The brain and spinal cord are the parts specifically affected, its action on the latter being evidenced by the tetanic convulsions to which it gives rise in poisonous doses. From Kölliker's experiments it is to be inferred that prussic acid directly paralyses the nerve-trunks, and probably, when given internally, it acts as rapidly on the nerve-trunks as on the muscles.

Dr. K. McLeod administered prussic acid to allay excitement in mania and insanity, and he claims that in a fifth of the cases so treated restoration to reason was to be mainly attributed to this medicine, although in the majority of his cases its effects for good were transient or inappreciable. Prussic acid exercises a beneficial effect in nervous irritability. Richter and Coates both testify to its efficacy in neuralgia from cold or when associated with a rheumatic tendency.

Toxicology.—Hydrocyanic acid is particularly noxious to vegetable life, and is poisonous to all animals, but rather less so to cold than to warm-blooded animals. According to Dr. Amory, horses are insusceptible to it, an opinion in which I am not prepared to coincide. Dr. Shattock states that half-an-ounce given to a hyæna was not sufficient to kill it.

Shradez, of Berlin, in 1802 first demonstrated the intensely pernicious properties of prussic acid. When given in doses poisonous but sufficiently small to admit of our observing its effects, it will be seen to produce the following train of symptoms:—Giddiness, loss of power over the muscular movements, a sense of constriction of the fauces and panting respiration; the head drops and the tongue protrudes; then come on spasms of the voluntary muscles, and of the heart and respiratory muscles, if the dose given be sufficiently large; the face is now livid and bloated, the eyes are protruded, the veins are intensely congested, and death almost immediately ensues, being often preceded by a peculiar shriek or cry.

If the dose be not large enough to produce these symptoms, the spasms may relax and paralysis may supervene, and continue until death releases the victim; generally, however, convulsions at intervals occur previous to death. The convulsions induced by prussic acid are due to derangement of the functions of the cord, and probably to disturbance of the cerebral circulation. Cases are recorded in which prussic acid immediately induced a profound stupor, and almost instantaneous death without convulsions, the functions of the nerve centres and of the heart appearing to be simultaneously arrested. If a patient recovers from poisoning by prussic acid, the symptoms during convalescence are not unlike those in recovery from opium poisoning, but the condition of the pupil is variable. Prussic acid acts locally as well as generally, and is equally fatal whether administered by the mouth, rectum, vagina, applied to wounds or to the conjunctiva, or inhaled in a concentrated form. Prussic acid is not cumulative; on the contrary, use of it establishes a tolerance. The smallest fatal dose will vary with the degree of dilution in which it is used, the strength of the person to whom it is administered, and, if it be given by the mouth, the fulness or emptiness of the stomach; death has been occasioned in a man by a mixture containing scarcely a grain of the anhydrous acid.

In poisoning from small doses, blood may be found, on *post-mortem* examination, in all the cavities of the heart, and especially in those of the right side, but in cases of sudden death from very large doses, the left side of the heart will be found empty and contracted, while the right cavities contain blood, and are often distended. All the veins, but chiefly those of the brain, are remarkably engorged in prussic-acid poisoning. We have already alluded at some length to the changes induced in the blood by this substance. Cadaveric rigidity is greater after poisoning from hydrocyanic acid than in death from any other cause, and glistening of the eyes has been spoken of as characteristic in death produced by this poison. The odour of the acid is generally easily perceptible. Kölliker concludes from his experiments that hydrocyanic acid primarily induces cerebral paralysis and then destroys the reflex, and then the motor functions of the cord, and that it paralyses the heart, and permits it to become distended with blood.

The cause of death in the majority of cases, is obstruction of the respiration and the static congestion of the pulmonary tissue, which is revealed on examination is either a *post-mortem* appearance, or is due to asphyxia. Probably to asphyxia also, and not to the direct action of the poison, is due the cerebral and spinal apoplexy. According to Amory, (a) death is probably partly attributable to a state of blood-poisoning.

With regard to the antidotes and restorative measures to be resorted to in cases of poisoning with prussic acid, a few words are needed. Nunneley says he knows of no antidote to this poison, and that he has found chlorine useless. Orfila regards inhalation of ammonia, as suggested by Dr. John Murray, to be decidedly advantageous; at all events, it can do no harm. Messrs. Smith and Co. the eminent pharmacists of Edinburgh, have proposed as an antidote freshly precipitated oxide of iron with an alkaline carbonate. Their remarks on the subject may be found in the *Pharmaceutical Journal* for November, 1865. Preyer regards atropia, as physiologically antidotal to prussic acid, and he suggests the subcutaneous injection of it in doses of 1-75th of a grain. The grounds on which he bases his opinion are as follows:—Prussic acid kills by embarrassing the heart and respiration, and this it does by effecting an intense irritation of the inhibitory cardiac and pulmonary branches of the vagus: atropia paralyses these, and hence its antidotal power, notwithstanding the recent writings of Boehm, (b who dissents entirely from Preyer's views. I have only to affirm that, from my experimental observations on the lower animals, I would hopefully resort to the hypodermic administration of atropia, if called upon to treat a case of prussic acid poisoning. The employment of electricity and galvanism have been suggested, but even if efficient, the poison usually acts too quickly to admit of their application. Venesection has also been recommended, but the writer is not in a position to offer an opinion as to the utility of this measure. We have yet to mention the two most efficient means for counteracting the baneful effects of prussic acid in artificial respiration, and the application to the chest and shoulders of the hot and cold douche alternately; these are undoubtedly the best means of saving life, and should always be *immediately* resorted to.

(a) *Practitioner*, April, 1872.

(b) See the Author's "Reports on the Progress of Therapeutics" in the *Edin. Med. Journal* for Jan. 1875.

Nitrobenzole in large doses kills as quickly as prussic acid, and gives rise to very similar symptoms.

Cyanide of Potassium taken internally is converted by the acids of the stomach into prussic acid, and hence acts similarly; it does not kill so quickly however, and the insensibility induced by it may not come on so soon.

WEDNESDAY, AUGUST 9, 1876.

THE RIVERS' POLLUTION BILL.

Some anxiety appears to have been expressed as to the fate of the Rivers' Pollution Bill and the action of the Government in securing better water for rural districts. We gather from the authoritative utterances of the President of the Local Government Board, that the present impure and deficient water supply so keenly felt in some parts of the country are chiefly due to a sort of water famine. There are numerous reports as to the mischief arising out of a general inadequate supply, as well as to its polluted condition, in numerous rural districts. Mr. Sclater Booth speaks of embarrassment produced by a deputation, introduced by Dr. Lyon Playfair, urging Parliament to stay further legislation, and grant another Royal Commission of inquiry. It is clear that nothing would be gained by the adoption of such a recommendation, as Government and Parliament are in possession of ample information on the impurity and short supply of water throughout the country. Local authorities must be made to move in a matter of so much importance. They can now obtain loans to any reasonable amount to aid the work of improvement. The Rivers' Pollution Bill will give increased powers, and must strengthen the Water Bills of 1874 and 1875. A good deal more is required besides talk from deputations, for it is reported that the rains of the last few days have again brought down from the upper portions of the river Ribble an immense quantity of deleterious matters from the works situated on the banks about Clitheroe, Burnley, and other places in East Lancashire, and the consequence is that an immense destruction of fish has taken place. It is evident, also, that stringent regulations are required with regard to the use of contaminated water in dairy-farms; for we learn, on the authority of Dr. Stevenson, that three cases of milk-poisoning occurred during the past month in the parish of St. Pancras. The mother of one of the patients complained that the milk was dirty and, on further inquiry, it was discovered "that the cows had access to a pond containing crude sewage, a culvert opening directly into it, and bringing sewage from some twenty houses in the village," where the farm is situated. The garden also "surrounding the house is skirted with a sewage ditch, which ends in a brick culvert as it passes through the farm-yard, and discharges into the pond before mentioned. In the garden itself is another pond containing a few inches only of water. There is a shallow fifteen feet surface well, containing a few inches of filthy water; and from either one or the other of these sources is the water supply derived." With this water the milk-pails are washed out, and the dairy, so called, is simply an offset from the scullery of the house. Can it be otherwise than that the milk should be liable to produce fever?

◆

DR. HIME'S REMARKS ON "RECENT CHOLERA REPORTS."

We feel called upon to give a brief reply to Dr. Hime's criticism published last week on one of our articles on "Recent Reports on Cholera," but confess that had not those articles appeared, to use Dr. Hime's kind expression, "in all the power of editorial type," we should certainly not have taken any notice of the somewhat rude remarks he has thought proper to make. As, however, these articles are appearing in an editorial form, we should be the last to shirk the responsibility we have undertaken in publishing them, or to admit, by our silence, that they are open to any serious objections. Besides, the professional position and qualifications of Dr. Hime, and what he has already done in the field of medical literature, warrant us in regarding him as an adversary with whom we can have no objection to break a lance. Indeed, we are tempted to say that the very number of the Latin and even French quotations to be found in his "Remarks," are alone sufficient to claim from some people an acknowledgment of his learning and abilities, however much we may think him wanting in good taste.

The passage in Dr. Hime's remarks with which we have most reason to complain is as follows: "The writer is a strong believer in infection by means of impure water, but adduces very unsatisfactory evidence in support of his opinions. One would hardly have anticipated a resuscitation of the Broad Street pump, yet here we find it trotted out as the writer's *cheval de bataille* at the head of his forces." This statement is not only unfair but very misleading. Anyone who reads it, especially in connection with other passages in his remarks, and without having read the original articles, would naturally suppose that we are not only, as Dr. Hime asserts, strong believers in the infection of cholera by means of impure water, but that the main object of the article referred to was to support that opinion by all the evidence we could bring forward. Now nothing could have been further from our minds, nor do we think an impartial reader would consider that we had any such intention. To tell the truth, we are by no means "a strong believer" in the "drinking water theory" of cholera, as it is called, and certainly not to the extent to which some writers, without any reservation, would carry this theory; although we do believe that drinking impure water *may*, under certain exceptional circumstances, be a means of propagating the disease. And even if we had been a strong advocate of that theory, and had wished to make it a prominent subject of discussion, and to have brought forward all the arguments we could in its favour, we hope Dr. Hime will give us more credit for tact and judgment than to suppose we should have been satisfied with the one or two brief references which we made, or with only devoting a short paragraph to the consideration of so important a subject. Our object in writing those articles was not to discuss the merits of any theory, but to give a brief sketch of the more recent and generally received opinions respecting the mode of propagation and prevention of cholera, in connection with some recent reports and with that monograph of Pettenkofer which Dr. Hime himself has edited and translated. Therefore the apparent overrating of one theory more than of another could matter little in a series of articles, the object of which was to direct the reader's attention, not only to the proved and undisputed, but also to the *possible* or presumed, conditions by which this terrible disease may be propagated, and to the possible or presumed conditions by which it may be prevented. It is even possible that in the haste which is often incidental to journalistic writings, we may have made use of an expression which we might not under other circumstances have adopted. And perhaps the epithet "striking" is not so applicable to the illustration we referred to as to other important evidence that has been from time to time adduced to prove the influence which impure water may have in the production of cholera, and which evidence we might have brought forward had we intended to enter upon a full examination of the subject. But we should like to know what would become of periodical literature, if an editor was to be called to account for every expression that did not chime in with the prejudices and peculiar views of his correspondents?

This is not the place to enter into an argument with Dr. Hime as to the value or not of the evidence that has been adduced in favour of the "water theory;" but we may remark that we by no means regret having briefly alluded to the investigations of Dr. Snow, and at having said what an important part "this agent (water) may play i the diffusion of cholera." We made no especial allusion to the Broad Street pump, but if the evidence brought out in connection with that well is of that worthless nature which Dr. Hime would have his readers believe, it is strange that the committee appointed by the Board of Health to investigate the circumstances of the epidemic of 1854 should have formed such a different opinion as to report that—"It seems probable that the water of this well did really act as a vehicle of choleraic infection." It is also remarkable that such good-for-nothing evidence should have been "trotted" out (as we find it is) in one of our largest and most recent text-books on medicine—viz., "Reynolds's System of Medicine," and still more recently described at length in Macnamara's "History of Asiatic Cholera" just published. In that work Mr. Macnamara "evidently does not think it (the pump evidence) used up," for he remarks, "Dr. Snow's Broad Street case was a remarkable illustration of the influence of contaminated water in spreading the disease. Doubtless, the choleraic dejection of the first patient in this locality had passed into the well of the Broad Street pump, and had affected many of those who partook of the water." At all events, the circumstances connected with this well were of a very suspicious nature. But in Dr. Hime's version of the story there is a suppression of one or two important facts—a *suppressio veri*, as Dr. Hime would say, so that his statement appears to justify him in throwing ridicule upon the whole evidence.

In conclusion, we may observe that the theory which would imply the occasional transmissibility of cholera by means of contaminated water cannot be so easily shelved, as Dr. Hime would have us believe, nor can it, in the interest of the public health, be so disregarded as it might be if Dr. Hime's views on the subject were generally entertained. Nor can we feel any surprise that, at the International Sanitary Conference, held in Vienna, it was unanimously adopted "that cholera can be propagated by drinks, particularly water." On this point also Mr. Simon, whose authority on all questions connected with sanitary science, will not be disputed, is very emphatic. In the memorandum which Mr. Simon addressed to the Lords of the Privy Council in 1871, he says: "The dangers which have to be guarded against as favouring the spread of cholera-contagions are particularly two. First, and above all, there is the danger of *water-supplies* (the italics are his own) which are in any way the slightest degree tainted by house refuse, or other like kinds of filth; as where there is outflow, leakage, or filtration from sewers, house-drains, privies, cesspools, foul ditches, or the like into streams, springs, wells from which the supply of water is drawn, or into the soil in which the wells are situate—a danger which may exist on a small scale (but perhaps often repeated in the same district) at the pump or dip-well of a private house, or on a large and even vast scale in the source of supply of public waterworks."

THE VIVISECTION BILL,

Or, as it is to be called, "the Cruelty to Animals' Bill," will, the Chancellor of the Exchequer said, come on for reading on Tuesday or Wednesday. It was stated at Sheffield on Thursday last at the British Association that a satisfactory solution of this difficult question has been arrived at. The facts urged upon Mr. Cross by the deputation that waited upon him last week has been conceded, and a bill of more moderate pretensions will accordingly be passed. At the dinner held in Cutler's Hall, the veteran statesman, Mr. Roebuck, in reply to the toast of the borough members, after paying a tribute to the noble services rendered by the medical profession in alleviating the miseries of humanity, went on to say that remembering this, he had been startled to find the legislative body of which he had the honour to be a member so far misunderstanding the profession as to put them under the superintendence of the police officer. He should have thought that any man who had come to the age of a man could have trusted the medical profession not only to guide themselves, but also others, without the guardianship of those officers of the law. The profession, he believed, was able and willing to conduct experiments without giving any unnecessary pain. Their sole object was to obtain such knowledge as would benefit humanity, and this they tried to do with the least possible amount of pain, even when experimenting on the lowest animals. He thought Parliament might have conceded to the profession the power of deciding whether experiments and the pain connected with them were or were not necessary. But many good people let their sympathies run away with their judgment. He had no doubt pain was inflicted upon the lower animals; but the medical men felt greater pain in its infliction. After long observation and experience he could answer for the kindness, generosity, and benevolence of the medical profession. No body of men were more likely to conduct themselves with prudence and humanity towards either the higher or the lower animals. He regretted that an unnecessary stigma should have been inflicted upon the profession. It was true that man was somewhat selfish; but the medical profession should not be singled out, and the policeman set at the door. Parliament would have done better to have put trust in benevolence and kindness.

◆

Notes on Current Topics.

The Projected City of "Hygeia."

We were somewhat startled one morning, when looking over the papers we saw that Dr. Richardson's ideal city of health was likely to have a more tangible existence than in the fertile imagination of that eminent physician, and that the idea of establishing a sanitary city will be shortly put into execution. We are informed that a site has been obtained on the coast of Sussex for this proposed city, and that the suggestions made by Dr. Richardson will be carried out as far as practicable. It is even stated that the plans for all the public and private buildings required are being prepared by a well-known architect. How the capital for carrying out such a gigantic and expensive undertaking is to be procured we will not venture to say; but should it be under the fostering influence of a joint-stock company, we hope intending shareholders will warily scan the prospectus, and carefully consider the *pros* and *cons* before embarking in such an enterprise. At the time that Dr. Richardson's address was attracting so much attention, we gave in the columns of the *Medical Press* a general account of his scheme, and ventured to criticise the principles which laid at the foundation of it and the sanguine expectations which were held out in the event of its being actually carried into practice. The proof of the pudding, however, is in the eating thereof, and, in the interest of humanity, we should be glad to find that we had been much mistaken in the judgment we have passed upon this ideal city of health. We live in an age in which the experimental philosophy is being pushed to a degree of which, even Bacon himself could have formed no conception. This will be really an experiment on a gigantic scale, and such as we should have expected to see projected by our American cousins rather than by our own less venturesome countrymen.

Medical Officers of Health.

In the House of Commons last Friday, and in reply to Dr. Cameron, Mr. Sclater Booth stated that, under the Act of 1872 the first appointments of medical officers were for a period of five years, and the experimental period was adopted in order to see whether the arrangement was satisfactory, or whether any change would be desirable. He agreed that the efficiency of an officer was increased by the permanency of his appointment, and the practice was to sanction permanent appointments where the medical officer of health devoted his whole time to his duties. In cases where he did not devote his whole time he (Mr. Sclater Booth) thought that the rule of five years would be convenient.

In reference to this statement, we may remark, that there have been some instances in which the arrangement has been by no means satisfactory, and in which a change would certainly be desirable. We allude more particularly to the question of salary. Only recently the Regisrar-General drew our attention to the liberality of the Town Council at Blackburn, who, although their town contains about 80,000 inhabitants, fixed the salary of their medical officer of health at £25 per annum! Then, again, we rather think that the appointment should be permanent, whether the medical officer was devoting his whole time to his duties or not. If, as Mr. Sclater Booth admits, the efficiency of one officer is increased by the permanency of his appointment, then it follows that this condition would have the same effect if his duties only occupied a part of his time as it would have been were his whole time devoted to them. The appointment being a permanent one, bringing him in a small but certain addition to his income, and being worked in connection with his other professional duties, he would, under these circumstances, take more pleasure in, and devote more energy to the work required of him, than if he was liable to lose his appointment through the caprice or prejudices of the local authority, or through the influence of some aspiring rival.

Measles in Fiji.

We are sorry to hear the Fijians are already paying the penalty unfortunately incidental to the intercourse of savages with Europeans, and we regret that the negligence of the surgeon of the ship stationed off those islands is supposed to have precipitated an event, which we fear is to be regarded, under the above circumstances, as more or less inevitable.

It appears that last December Earl Carnarvon, in a letter to the Admiralty, said he was unable to form a decided conclusion as to the proportion of blame attaching to the Naval and Colonial authorities for the introduction by her Majesty's ship *Dido* of measles into the Fijian Islands. His own opinion was that the greater portion of the responsibility rested on the Colonial authorities. No one, unfortunately, seemed to be aware of the serious nature of the disease when freshly imported among the native population. He could not altogether absolve the captain or doctor of the ship from blame, and he had informed them that he disapproved of their not having treated the matter more seriously. It was treated as a mere child's disease, and no proper precaution taken to prevent communication, the result being a very large loss of life.

Tartar Emetic Mistaken for Cream of Tartar.

At Ballina petty sessions a few days ago, a chemist was remanded on the charge of selling tartar emetic for cream of tartar. Five persons were nearly fatally poisoned through the mistake. This is by no means the first time such mistakes have occurred, and in some cases of the kind the error may be excused on the ground of the similarity in the official names of drugs that present a wide difference in their potency. But in the present instance, the mistake was hardly excusable, as the name *antimonium tartaratum* bears no resemblance to that of *potassæ tartras acid.* The liability, however, of chemists to make these mistakes shows how careful the compilers of our Pharmacopœia should be in framing their nomenclature, particularly as changes are being constantly made in that respect. We often wonder some mistake is not made in the dispensing of calomel and corrosive sublimate, considering that the former is only called the subchloride, and the latter the perchloride, of mercury.

Public Opinion and the Vivisection Bill.

The *Globe* says that "though the Vivisection Bill should not pass this session, its discussion has had a profound effect on the profession and the country. The unwritten law of public opinion is hardly less effective than the written law of public enactment. The effect of such important measures being kept before the public is an element in the political education of the constituencies. It is mortifying that important measures should be lost through preventible causes, but the cloud has its proverbial silver lining. The postponement of legislation often achieves great public ends, and the legislation itself is made more lasting and effective." This is all very well, and we quite agree with that paper when it says that the "unwritten law of public opinion is hardly less effective than the written law of public enactment." But before we are convinced that this law is a righteous law, we must know that this public opinion is genuine and of a spontaneous growth, and not, as it often is, a plant which is only to be found here and there, and which has been forced into notice under the fostering influence of a few conceited and time-serving agitators. Moreover, this observation of the *Globe* cuts both ways; for if the law of public opinion is so powerful, surely the doings of such a body of men as that of the medical profession may be safely committed to the control of that law, without being hampered by a very objectionable law of public enactment.

Quinine in Parturition.

In the July number of the *Virginia Medical Monthly* there is a very good and temperate paper on the above subject from the pen of E. T. Easley, A.M., M.D. Although not agreeing with Dr. Monteverdi, who concluded from his extensive series of experiments published in 1871, that quinine was capable of originating uterine contractions, Dr. Easley is convinced that this alkaloid has undoubtedly the power of augmenting uterine action *after it has been originated*, whilst he is equally confident of the prophylactic influence of quinine over the fevers incidental to or complicating child-birth. As it is not capable of originating uterine contractions, it may be administered in all stages of pregnancy without the fear of any such result. During actual labour, however, it is sometimes preferable to ergot; while it is, according to his experience, very useful in the exhaustion following tedious labours, and in the treatment of the child-bed fevers.

It has been said that quinine, as an ecbolic and parturient agent, affords greater security both to mother and child than ergot does, that its effects are more easily controlled, that the contractions it occasions are more nearly normal, and seldom or never inordinate, and that, moreover, its prophylactic virtues should also be taken into account. That this drug will ever take the place of ergot—the bad effects of which have been very much overrated—we very much doubt; but of its therapeutical properties under the other circumstances above mentioned, there can be only one opinion; and we know that as a tonic, antipyrectic, and prophylactic agent, it is much used in the lying-in room by most obstetric physicians of the present day.

The Irish Prisons' Bill.

Few of the provisions in the new Irish Prisons' Bill appear calculated to give rise to any apprehension or uneasiness in the medical mind. There is, however, one section which will probably undergo considerable modification before it is permitted to pass into a law. According to this (23rd) section, it shall be lawful for the General Prisoners' Board from time to time, by order, to transfer any officer or servant of an ordinary or a convict prison to any other prison, or to the office of the General Prisons' Board in Dublin, and to require such officer, &c., to discharge like duties or duties analagous to those previously discharged by him; and any such officer or servant refusing to be so transferred shall be deemed *to have resigned* his office, and shall *not be entitled* to the grant of any *superannuation* allowance or *compensation.* The committee of the Irish Medical Association have directed the special attention of the promoters of the Bill to the reasonableness of exempting the visiting medical officers from the operation of this section, and it is remarkable that no similar or corresponding provision is to be found in the English Prisons' Bill. If this proviso were to become law, it would evidently be competent for the General Prisons' Board at any moment to get rid of a visiting medical officer, and to deprive him of his rightful compensation or superannuation, by ordering his transfer to some prison at a distance from his locality of practice, and medical officers would thus become at once simple tenants at will, under the General Board. The Chief Secretary has promised consideration to the objection raised by the council of the Irish Medical Association, and as we conceive that it was never intended to include under this rule officers who do not give their whole time to their prison duties, we anticipate that the clause will be amended.

Surgeons for the Eastern Wars.

In reference to the satisfaction produced at Belgrade by the arrival of two English surgeons there, a correspondent of the *Daily News* writes to say he had a letter from a friend last night, dated Belgrade, which was of course written before the arrival of these surgeons, and in it he says:—"If you hear of any young surgeon wanting practice in operations, &c., he ought to come out here. I was particularly told this morning that any English surgeon would be gladly welcomed and immediately employed by the Government." In another letter I had from him a few days since he says:—"I have done a little work in the hospital, and I have written praying that an English ambulance might be got up. The want is dreadful. If half-a-dozen good stout English nurses would come out they might do much. I am afraid that at present all the severely wounded are left in the field." He also says:—"The rumour that a public meeting is to be held in London has caused the liveliest gratification here."

Witchcraft in France.

The *Globe* draws our attention to a case recently tried by the Correctional Tribunal of Montbrison (Loire), and which reveals the fact that the belief in sorcerers still lingers in some parts of France. A man named Jean Baron, 37 years of age, a small landed proprietor of Poncins, believed that for the past two or three years he had been the victim of occult influences from some of his neighbours, whom he suspected to be jealous of his prosperous condition. His cows were constantly ill, and the mere sight of the supposed sorcerers was sufficient to make him so unwell that, as he said, he got on the point of death. In vain he had consulted some distinguished physicians, going even to Lyons for the purpose; and he finally resolved to put in practice the advice given him by some reapers the previous year—being to draw some blood from the sorcerers in order to break the charm. He therefore waited his opportunity at church, and after service rushed at those whom he accused of the witchcraft, struck them several blows, and then ran some steel pins deep into the flesh of each of his assumed enemies. He was, in consequence, cited to appear before the Tribunal for these acts, and he admitted having driven pins into a man named Raynaud and his wife, and a girl named Jeannette Badieu, but denied the blows, explaining that he had no occasion to give them; all that he wanted was to draw a little blood; "which," said he, with a joyous air, "I managed to do, and since that period I am perfectly cured, as well as my beasts." Notwithstanding the efforts of the President to make him understand that there were neither sorcerers nor witchcraft in the world, he could only obtain this reply, "But I was ill every time I met them; and now that I have drawn some blood from them their sight produces no effect whatever on me, and I am perfectly cured; I have, therefore, reason to believe that they had cast on me an evil eye." The penalty of 15 days' imprisonment inflicted on him did not in the slightest degree disturb his serenity, happy at having re-established his health at so cheap a rate.

A few months ago we made in the columns of the Medical Press some editorial comments on a similar case which occurred in this country at a place called Long Compton, in South Warwickshire. At that time we remarked that "when a form of superstition has for ages, and almost in every clime, dominated the human mind, it must necessarily take some time before it completely succumbs to the influence of an enlightened rationalism and an advanced civilisation;" and perhaps these remarks are still more applicable to a country in which the education of the masses has even made less progress than it has with us, and in which even the middle and upper classes of society are by no means free from much credulity and superstition.

The Recent Hot Weather.

We seldom have a few hot days in the summer months without the daily papers giving their readers some advice as to the best way of living and of being comparatively comfortable under high ranges of temperature. A few days ago the *Daily Telegraph* had a leader on the subject, and now the *Times* follows up with another. The advice which our respected contemporaries give is, on the whole, very good, but we are afraid their readers will serve them much in the same way as our patients often serve us, that is, listen to them with great deference and attention, but by no means follow their advice. The fact is, hot weather in this country is generally of so short duration that people do not think it worth while, or will not take the trouble, to alter their usual mode of living on account of changes of tèmperature which are not likely to last long. The observations of the *Times*, especially as regards excesses in eating and drinking, are, however applicable to the whole summer season, and there can be no doubt that the health and comfort of the public would be much promoted by their living more in accordance with the temperature that surrounds them. At all events the lay papers do a good service in a hygienic point of view by giving through their widely-circulated columns greater publicity to those physiological laws of health which are only known to a few. Besides, people generally think more of and pay more attention to what they see in print than to what is told them by their medical advisers. And as respects our medical writings, for one person who reads a medical book a thousand will read a leader in a popular journal.

The Sale of Poisons.

A contemporary (*The Globe*) says:—

"It is a question of growing importance whether the sale of poisons has not been granted too much freedom. In some cases the regulation providing for the inscription of purchasers' names in a book is quite inoperative as a public safeguard. To cite one instance, a gentleman lately applied to a leading chemist at the West-end, by whom he was well known, for two ounces of tartar emetic, by way of proving whether so large a quantity would be dispensed. The chemist made no difficulty at all about the matter. His acquaintanceship with the applicant was sufficiently close to justify compliance with an even larger order. Of course, the name of the purchaser would have to be recorded in the ledger kept for that purpose. When this formality was complied with, the vendor would be free from blame, whatever consequences might result from the transaction. The weak point in this sort of safeguard is, that it takes no account of such mischances as a sudden aberration of intellect. Supposing, for instance, that the applicant in question had secretly developed a homicidal mania, the transaction placed in his hands the power of taking thirty or forty human lives. The fact of his mind being so diseased he would, of course, carefully conceal from the chemist, in accordance with the invariable habit of the insane. We do not mean to say that such danger is of common occurrence, but it cannot be questioned that homicidal maniacs enjoy ample means of gratifying their cravings before their insanity becomes manifest. This is not the only risk involved in the sale of poisons under lax restrictions. Taking the same drug as an example, we find that tartar emetic is commonly and largely used in West end stables to give horses a glossy look. We will suppose that a owner of a good-sized stud procures from a chemist two or three ounces of this poison, and forthwith hands it over either to his coachman or head groom. In all probability the recipient will place it in the harness-room, or if he be of a cautious sort, in some apartment of his own house. Who, in this instance, would be responsible, in the event of any accident subsequently arising through the drug having been stolen and applied to evil purposes? Not the vendor; he complied with the Act. Not the purchaser, who only did what the law allowed him to. Not the recipient, his part in the affair being only that of an intermediary agent. Hence, if the thief could not be discovered—and it would be very difficult to do so under such circumstances—no one would be to blame for a wholesale dissemination of poison."

The Metropolitan Hospital Sunday Fund.

The Hospital Sunday Fund has now reached nearly £29,000, and money is almost daily sent in to the secretary. This is very gratifying, since it exceeds the amount received last year by nearly £3,000. The Committee having arranged an earlier distribution of the bulk of the money in hand, namely £26,280 6s. 8d., what may accrue hereafter is to be apportioned on the same basis at a later period of the year. Of this sum £23,943 10s. is divided between sixty-nine general and special hospitals and four convalescent institutions, and £2,336 16s. 8d. to forty-five dispensaries. The Committee, it appears, having freely invited the representatives of any hospital or dispensary to confer with them in every case in which there was any supposed cause of complaint, those who availed themselves of the opportunity decided upon leaving the decision entirely in the hands of the Committee of Distribution. The only institution that has actually been injured by the Hospital Sunday Fund is the Holloway and North Islington Dispensary. On making an examination, and taking the average of the past three years, we find the loss sustained rather over £250. This we venture to think should be remedied, for there is no reason to permit even one well-conducted institution to be any way a sufferer or loser by the Hospital Sunday. We venture also to suggest to the Committtee that no institution should be entitled to be called or classed among hospitals if it merely administers out-door relief and does not receive *in-patients.*

The Manner of Interment of the Ancient Irish.

From the MS. of O'Connor's "History of Ireland" we extract the following :—

"Eochaid X. was called Aremh, or of the grave, because he first regulated the different modes of interment. He directed that the head should be placed on the west, the foot to the east, and a Leacht, or monument of stone, raised over the whole (Trichiorgaoithe an bhas, lib. 3, halt 8). Some knights had graves dug, the bottoms of smooth marble, the sides built with brick and cement, in the form of a modern coffin, and so finished at top that a large stone so exactly fitted it as to leave no room for dust, &c, to enter. The corpse had all armour on, both offensive and defensive. Inscriptions of very beautiful sculpture were raised round the moulding of the coffin, as may be still seen at Ardfeart, or the lofty burying-place in Kerry. Foreigners of distinction, or those who fell by the sword, had Leachts, or rather carn, raised to them, according to this maxim of Pythagoras, who was himself a Druid, 'Locus lapidibus obtinendus, ubi sanguis humanus sparsus est.' When Cuchullain was mortally wounded he directed his charioteer 'to carry him to yonder carruig (a large stone pitched on one end), to place his body standing against it, his sword in his left hand, his shield raised up, and his two spears by his left side.' The renowned hero, Eogan, slain at Lena, was thus laid out, and a carn raised over him. The following verse in the history of the battle of Lena shows Eogan 'placed erect, his launce by his shoulder, his helmet on his head, his coat of mail on his body, and his sword in his hand.'"

The Perils of Quackery in France.

The *Temps* of the 17th ult. contains a curious report of the hearing, in a French correctional court, of a charge of swindling against a German named Baer, who had become naturalised in France, and whose name is associated with the sale of "Eau antineuralgique." This compound is alleged to cure neuralgia, prevent apoplexy, and combat epilepsy. According to the report of Dr. Bergeron, it consists of bad eau-de-vie, in which tobacco previously exhausted with boiling water has been macerated; to this a little indigo is added. The remedy is sold in 4s. bottles, but sample bottles are considerately provided at 2s. 6d. each. In the course of his explanation the accused asserted that the water had produced "des résultats très-grands," a remark which met with the concurrence of the prosecution on the ground that the proceeds of its sale amounted to 1,800,000 francs yearly! The charge of swindling was established, and the accused was sentenced to one month's imprisonment. Oh! for a little wholesome despotism in our own little island, and a little less of that form of paternal government which patronises the imposition of these nostrums upon the public so long as the proprietors are able to purchase such patronage by payment of a tax. Are there not scores of nostrums as fraudulent as the bad tobacco-water of the German quack sold every day and from year to year without interference, nay, rather under the authority of English law? And yet the British consumer is supposed to be able to protect himself, while the Frenchman is guarded by the Government against such impositions.

How to make Leeches Bite.

EVERY practitioner must have found how difficult it is at times to make leeches bite, and perhaps the following method, which we take from a recent number of *Le Progrès Medical*, may interest our readers :—

"In order to make leeches 'take' immediately we should put them into a glass half filled with cold water. We should next carefully bathe with warm water the part to which we wish to apply the leeches, and then quickly apply the glass to the skin. By this means the leeches will attach themselves to the skin with surprising rapidity, the patient merely feeling one single bite. When all the leeches have taken, the glass should be removed in such a manner as not to wet the patient. To accomplish this it will be sufficient to receive the water at the most depending part into a sponge. If we wish to apply the leeches to only a very limited surface, all we need do is to place on the glass previously to its application a sheet of strong paper with a hole cut in it of the required size."

The Vivisection Question.

THE *Gardener's Chronicle* remarks of the Vivisection Bill:—"Doctors are not the only people who should look to the clauses of the Vivisection Bill, which some well meaning but utterly inconsistent and wrong-headed enthusiasts are striving to push through Parliament. No one would uphold reckless wanton cruelty, least of all physiologists and doctors—the latter, without exception, the most self-sacrificing class of the community, exposing as they do daily their lives and those of their families to risks that the general public know nothing of. To treat the numerically insignificant experiments of the man of science, when they are undertaken for the highest objects, not for sport or food, as penal, or at least as objects of police supervision, is an utter absurdity on the part of any one who wears a coat of cloth, not to say a sealskin jacket or a feather-trimmed hat, who eats a mutton-chop or an oyster, who indulges in the sport of shooting, hunting, or fishing, or sets traps for rats, rabbits, or moles. As for the gardeners, there must be no smoking of houses, no catching of slugs and snails, no trapping of woodlice, weevils, or earwigs; green-fly, scale, and thrips must be allowed to enjoy their lives unmolested. Indeed, as it is quite impossible to draw the line between the different manifestations of life, animal or vegetable, we may next expect to hear it gravely proposed to be made a punishable offence to cut a cabbage—certainly to prune a peach-tree or pollard a willow : an *argumentum ad absurdum*, some will say, and truly so. All we can reply is, that it is not more preposterous than the proceedings of those who would allow a frog to be vivisected, but who draw the line at cats and dogs"

The Profession at the Antipodes.

ALCOHOLIC stimulation seems to possess a peculiar charm for our Australian brethren if we are to believe the reports which reach us in the journals of that country. Within the space of twenty lines in the last number of the *Melbourne Medical Record*, so many as three "thirsty-souls," two being the only practitioners in one town, and the third in another small township, appear to have imbibed rather heavily. Our contemporary treats the matter as though it were an every day occurrence, a subject for amusement in fact. The first case is summarised thus :—

Of the two medical men practising in ——— one is a Justice of the Peace. The J.P. doctor was one morning called upon to fine his brother medical for being "fou" the previows night, and finding his way to the lock-up. Dire was the rage and loud the threats of the fined one, but by the next evening they were both seen lovingly arm in arm wending their way in *a zigzag manner* up the township.

Of the other, three lines will suffice :—

Dr. M'C———has again been taken up for drunkenness, fined £1, and cautioned by the Bench that if he is brought up again he would be sentenced to three months imprisonment.

We are unfortunately not quite immaculate in Great Britain, but for the honour of our profession, we trust that these three medicos, the only three in fact in two small towns, are not *indices* of the rest of the country : if they are, heaven help their patients ! But we know this is not the case from personal acquaintance with several professional friends resident there. It may be, and probably is the fact that as there is so little to chronicle in a country sparsely populated like Australia, molehills become mountains, and these latter are made to reach the skies. No doubt there is some foundation for the reports given in our contemporary, and we are therefore sorry that they are so flippantly treated. If publicity was necessary it should have been in the form of a dignified rebuke, and an appeal to men, who, if they had no respect for themselves, might at least be induced to show some for the honour of the profession whose badge they wore.

STAFF-VETERINARY SURGEON JAMES COLLINS, of the Enniskilling Dragoons, is the newly-appointed Veterinary Surgeon-General of the Army. The appointment, according to the *Veterinary Journal*, has given great satisfaction.

MR. THOMAS PROCTER, of Elmdale, Clifton, has bequeathed £100 each to the Bristol General Hospital and the Bristol Royal Infirmary. Mr. T. Dyer Edwardes has given a second £100 to the Chelsea Hospital for Women. Under the will of the late Mr. W. Haigh, of Huddersfield, the Infirmary of that town receives the magnificent legacy of £3,999. The same Institution also receives £600 as a legacy from the late Mr. Joseph Hirst.

IN London, according to the Registrar-General's Report, the death-rate rose exceptionally high last week, viz., to thirty per thousand of the population. The deaths included 7 from small-pox, 38 from scarlet fever, 19 from different forms of fever, and 522 from diarrhœa; the seven principal diseases of the zymotic class causing 669 deaths, against 373 and 583 in the two preceding weeks. These 669 deaths were 137 above the corrected average number from the same diseases in the corresponding week of the last ten years, and were equal to an annual rate of 10·0 per 1,000. The fatal cases of small-pox, measles, scarlet fever, and fever were below the corrected average, whereas those of diphtheria, whooping-cough, and diarrhœa showed an excess. Fourteen of the 28 deaths from measles, and

17 of the 38 from scarlet fever occurred in South London. The 7 deaths from small-pox were one less than those in the previous week, and were all recorded in South London.

◆

BRITISH MEDICAL ASSOCIATION.

The Forty-fourth Annual Meeting of the British Medical Association took place last week, at Sheffield. On the Tuesday about 230 names were down as present in the town, and on Thursday morning the number reached its limit, 400. The proceedings were commenced in the usual manner by attending divine service in the parish church, where an appropriate address was delivered by the Rev. Dr. Gatty ; the text being chosen from St. Matthew's Gospel. "They that be whole need not a physician, but they that are sick." The rev. gentleman alluded to the evolution of man from the lower *animals* as not compatible with religious records. He touched also upon the question of intemperance—a degrading vice, peculiar to man, and at the present time a national disgrace—certainly no inheritance from a lower animal.

The annual general meeting was held in the banqueting room of Cutler's Hall, in the course of which Dr. de Bartolomé was inducted as President of the Association for the forthcoming year.

The annual report showed that the Association had lost 83 members by resignation, 51 by death, and that 726 new members had been elected.

With regard to the pecuniary position, the accounts showed that there had been an increase of receipts amounting to £740, but that the expenditure had increased upwards of £1,300.

A subject of some interest was referred to in the report. It may be remembered that at the general meeting in Edinburgh, it was resolved that a circular should be sent to the members of the Association to ascertain the general view with regard to the admission of women to the membership of the Association. Out of 6,250 circulars sent out 4,161 were returned, 3,072 against, and 1,051 in favour of their admission. Now, as the result of the replies to this circular is a matter of the greatest importance really determining the views of the profession as to the admission of women to the study of medicine, therefore it may be presumed that all who object have not failed to make their objection known. It would appear that one third of the whole profession are absolutely indifferent whether women shall be allowed to qualify or not, and of the rest one third are actually in favour of a qualification being granted to them. It then, appears, that whereas some three years ago the whole profession, with the exception of perhaps a hundred members, looked upon the admission of women as a degradation to the profession, and as a prelude to its retrogression. At the present time only fifty per cent. will trouble themselves to write one single word—"no," although upon that word depends whether or not they shall meet women on an equality to discuss subjects in medicine, surgery, and obstetrics.

We are at a loss to comprehend this sudden change, unless the reason be that our *confrères* have learned to respect themselves, and now conclude that should women ever be successful in getting their names on the register, they may perhaps supply a want, but they will not be able to displace men, except those who need displacing.

Another question treated of in the report is that of intemperance, a resolution having been passed at the last meeting "that excessive intemperance is in many cases a symptom of a special form of insanity, which requires special treatment, with a view (1) to the recovery of those affected, and (2) to the protection and advantage of them and society ; that in the present state of the law such treatment is not attainable ; and that it is desirable that legal provisions be made to render it attainable."

This resolution is now referred to a sub-committee, and it is proposed that petitions should be presented to Parliament early in the next session. The sub-committee have to consider a subject beset with difficulties, and it is questionable whether Government will be at all willing to support a Bill concerning which opinion will be greatly divided. It would be very gratifying, and would bring great *éclat* upon the Association, if the sub-committee should suggest any form of legislation which would diminish drunkenness, and be at the same time not intolerable.

The usual addresses in medicine, surgery, and public medicine given, are being reported in our columns, together with abstracts of some of the papers read in the various sections.

The town which has invited the Association this year is, perhaps, one of the dirtiest in the country. It lies in a hole entirely surrounded by hills, which jealously guard and prevent the escape of the thick smoke from the tall chimneys of upwards of seven hundred factories. The crowds and appearance of the population, and the class of the houses throughout the whole town, differ in no respect from the neighbourhood of St. Giles or Whitechapel. The disadvantages of the town itself were, however, soon forgotten or unnoticed, for the members of the Association almost without exception busied themselves by investigating the industries of the place. The large and wealthy firms showed extreme kindness and courtesy in receiving them at their various works, and in delaying the ordinary business for the purpose of exhibiting the more interesting manufactures of the department, and in answering the ten thousand questions of the curious.

Guns, armour plates, wires, railway lines, silver-plated teapots, and almost every variety of instrument have been specially manufactured for the instruction of the members of the Association. After inspecting the works within the town, excursions were made through the picturesque country around, and the many places of historical fame or other notoriety with which the neighbourhood of Sheffield abounds were visited.

◆

Literature.

ANNUAL REPORTS OF DISEASES OF THE CHEST. (*a*)

This work is to take the place of Dr. Dobell's "Reports on the Progress of Medicine in different Parts of the World," we are informed in the preface. These Chest Diseases Reports form a closely printed octavo volume of over three hundred pages, and the book has a very good index. It is so full of information that it rivals "Bradshaw," which is generally supposed to contain an unusually large number of facts for a book of its size. Moreover, it resembles "Bradshaw" in that it carries the reader over a good deal of country—British Guiana, California, Canada, China, Denmark and Sweden, Egypt, France, Germany and Austria, Holland, India, Italy, Russia, South Africa, Great Britain, and the United States being all laid under contribution.

And, by-the-way, we may suggest that the classification of the Reports would be much more convenient if it depended on the subject matter, than, as in the present volume, on the countries from which the reports come.

For instance, the reader wishing to learn all that he can of recent opinions about mountain air, will have to consult reports from three or four countries in different parts of the book.

We shall mention a few of the more important articles.

(*a*) "Annual Reports of Diseases of the Chest." Vol. I. 1874-1875. By Horace Dobell, M.D., assisted by Adolphe Wahltuch, M.D., and R. Shingleton Smith, M.D.

From France there is an abstract of the method of treatment of lung diseases by rarefied or compressed air, by Dr. Waldenburg's apparatus.

From Italy, notes of a paper by Dr. Malachin de Cristoforis, in which is the remarkable conclusion that "Electrolysis in aneurism has solely a palliative and symptomatic value." But we think that cases might have been found in the period covered by the Reports to contradict *that* statement.

The allusion to Electricity recalls the fact that two observers record unfavourable results of electric stimulation of the heart by needles passed into the organ—Dr. Vulpian (p. 14) and Dr. Mayer (p. 60).

The report from Great Britian contains a *précis* of Surgeon Welch's comprehensive essay on "Destructive Lung Diseases among Soldiers;" an abstract of Dr. H. Fagge and Dr. Dickinson's papers on "The Relation between Diabetes and Phthisis;" the discussion on the Similarity and Differences between Membranous Croup and Diphtheria; and many other notices of the work done by British physicians in this particular class of diseases. As home work is more familiar to the reader than foreign work, we pass over the rest.

From Canada, there is a paper by Dr. Howard disputing the accuracy of the opinions about the origin of tubercle which have been propounded by Villemin, Burdon-Sanderson, and others.

From Sweden, short notes on climatic matters.

Dr. Gordon sends an interesting account of the population, climate, and diseases of British Guiana, in which he records a death-rate for the whole colony in 1871 of 37.4 per 1000; for Georgetown in 1874 the rate was 51.8 per 1000! In August 1874, nearly 16 inches of rain fell on 17 wet days; the total rainfall for the year being rather over 10 feet.

The Californian report is taken up with statements as to the moistness of the air, but unfortunately no details as to the numbers of phthisis, and other pulmonary deaths, are given.

"Notes for Nile Voyagers" are sent from Cairo by Dr. Grant.

The most interesting part of the Indian report is that which relates to some native drugs, one of them, rejoicing in a name equivalent to "confection of squash," being very useful in hæmoptysis.

From South Africa Dr. Dyer sends a summer meteorological report very valuable to intending emigrants to the Diamond Fields.

And, lastly, the United States medical literature contributes." Notes of Laryngeal Phthisis," by Dr. Lincoln; "Treatment of Pulmonary Cavities by Injection through the Chest Walls," by an enterprising Dr. Pepper; a remarkable case of air in the pericardium; and to close the book, notes of the case of a woman who lived 16 days after the external rupture of a large aneurism of the arch of the aorta.

Similar volumes of annual reports of other kinds of diseases would be both interesting and useful, especially if arranged with more regard to the reader's time.

◆

ON OVERWORK AND PREMATURE MENTAL DECAY: ITS TREATMENT. (*a*)

A timely and well-written little book on a subject of great interest, of sufficient length to enter into detail, and yet not so long as to be tedious. The effects of overwork are first studied in relation to the structure and composition of the brain, then the statistics of mental diseases are given to show the results of advancing civilisation.

Dr. Routh points out the symptoms of overwork in the [illegible], the schoolboy, the hyperfecund mother, the busy [illegible]. Among instances of mental fatigue in men the author gives an interesting interview with Dr. Golding Bird six weeks before his death, in which he spoke of his full waiting-room, his large professional income, as being no matter for congratulation, seeing that he (Dr. Bird) felt himself a wreck at a little over forty: "My parting words of advice to you are—never mind at what loss—take your six weeks' holiday."

Next follows a fair and lucid description of the mode of action, administration, and uses of *phosphorus*, including its beneficial effects on skin affections, especially acne. As a sedative nitrate (*nitrite?*) of amyl is recommended, in doses of one drop, increased to four or five drops, in water. "It is very quieting, and does not leave the lassitude and heaviness of opiates, nor the depression of chloral."

A number of illustrative cases conclude this very readable work. The publishers must be praised for the attractive form in which it is issued.

(*a*) "On Overwork and Premature Mental Decay: its Treatment." By C. H. F. Routh, M.D., M.R.C.P. Second Edition. London: Baillière, Tindall, and Cox.

◆

TRANSACTIONS OF THE PATHOLOGICAL SOCIETY OF LONDON. (*a*)

Since Dublin first instituted a Pathological Society the number of kindred societies has greatly increased, and we believe are still increasing. That great and solid advantages arise from them admits of no doubt. We would not have the heads of the profession attending the meetings so regularly as they do if they did not afford valuable information. It is of a kind, too, which could not by any possibility be got elsewhere. The greater number of all the remarkable cases occurring within the week, and which, having proved fatal, have been examined, are exhibited within the space of from one to two hours. Nor is it to be forgotten that whatever explanation is put on a specimen by the exhibitor, the preparation is there—and usually recent—to speak for itself. Need we add how much precious time is thus saved? Many preparations, too, require much time for their proper exhibition, and so the time of the meeting is by so much economised. In truth the weekly meeting of a Pathological Society is neither more nor less than an accumulation of valuable practical information exhibited in the shortest possible time.

Whilst thus accepting the great value of these societies, we cannot, however, overlook the dangers to which they give rise. For there can be no doubt their tendency is to join into one things that are essentially distinct. We mean morbid anatomy and pathology. No greater mistake, we conceive, can be made. Our knowledge of the former has enormously increased within the last thirty years. But how has it fared with our knowledge of pathology? Has a single step been gained in this direction? Do we know more now how a fever affects us than we did at that period? Or why cancer attacks some individuals and not others? We see, indeed, the results of these diseases, that is, the morbid anatomy; but the causes are hidden as ever. "*Causa latet.*" And from all we see are likely to remain so. We make these remarks because, from the way some morbid specimens are now exhibited, and the minute details given as revealed by the microscope, the impression might go abroad that these details were the real pathology of the matter.

There is still another point, too, in the investigation of morbid changes which must never be overlooked—we mean the marked differences which obtain in different individuals as to the results of disease. An amount of disease which will kill one will be comparatively harmless in another. We might take pneumonia as an example. Persons will die, too, of typhoid fever, and yet the morbid changes found may be of the very slightest. And so of other diseases. It follows from this that our morbid specimens are not always to be regarded as the sole cause of death, but that there is a something over and above to be taken

---

(*a*) "Transactions of the Pathological Society of London." Vol. XXVI. Comprising the Report of the Proceedings for the Session 1874-1875. London: Printed for the Society by J. E. Adlard, Bartholomew Close. 1875. Pp. 362.

into the account. This subject we might pursue farther did our limits allow of it ; but we must now proceed to notice the volume before us. It has fallen to our lot to have to speak of many of the preceding volumes of the same society, and we have always done so with pleasure, and this one is no exception to the rule. It is full of interesting cases both to physicians and surgeons. A few, a very few of these we now proceed to notice.

DISEASES OF THE NERVOUS SYSTEM.

Passing by No. 1, which was a tumour of the brain, and exhibited by W. Cayley, M.D., we come to No. 2, by C. De Morgan. It is entitled "Case of Multiple Neuroma of the Forearm," and is a very remarkable case. The patient was a female of 15 years of age, but had been seen in 1867, and from that date forward, as the disease advanced and the suffering of the patient increased. Finally amputation above the elbow was performed. The musculo-spiral nerve was found much diseased, with neuromatous tumours growing on it. We wish we could give this very rare case in full, but without the drawings this would not be possible. Besides the disease of the nerves there was great hypertrophy of the subcutaneous cellular membrane. The disease was congenital.

Amongst "The Organs of Circulation," No. 3, by S. Coupland, M.B., is worthy of notice. It is an instance of far advanced disease of the right ventricle and valves, and also the pulmonary artery. It occurred in a sailor who had spent many years in the navy, and had reached 75 years of age. He had never had rheumatism, and it would seem had not complained till within eight months of his death. The heart weighed nearly twenty ounces. There was very extensive disease of the pulmonary valves, and the artery measured more than six inches in circumference. Its coats were very thin. There was both dilatation and hypertrophy of the right cavities. The dilatation of the pulmonary artery extended into its branches, which also presented marks of atheroma. This case is well worthy of perusal. No. 5, by T. S. Dowse, M.D., is also a case of much interest. It is entitled "Aneurism of the Base of the Pulmonary Artery," and occurred in a female of only 19 years of age. She died of acute pericarditis, caused apparently by a rent in the sac of the aneurism, which was as large as a pullet's egg, and lay on the anterior portion of the pulmonary artery, the valves of which were completely eroded, and replaced by vegetative growths. It was possible the patient may have had syphilis, but under any aspect this case is very remarkable. The aorta was quite healthy. No. 6, by J. F. Goodhart, M.D., is one of thoracic aneurism opening into the lung. We notice it, however, because, whilst the larynx was quite healthy, the trachea and some of its branches presented puckiness, and fibrous bands stretched across the walls of the tube, and to such an extent that the right bronchus was very considerably narrowed, the left being less affected. The lungs were quite healthy. The author thinks the morbid changes in this case were due to syphilis. This may be so ; but as urate of soda was found in each big toe, it seems to us it may have been gouty. No. 7, by W. Cayley, M.D., is entitled "Syphilitic Disease of the Heart." It was found in a gentleman of 28 years of age, who was found dead in his bed, and who had been in the habit of taking chloral. There was some hypertrophy of the left ventricle, and embedded in it and near the apex were several rounded dense nodules of a whitish colour, and which projected both externally and into the cavity of the ventricle. It is not stated whether the valves were healthy, or how far their action may have been interfered with by the morbid growths.

No. 8, by W. Cayley, M.D., is entitled "Extensive Disease of the Aortic Valves in an Infant." This is a very rare case, and was congenital, for from birth the breathing was oppressed. The infant lived to be nine months old. A loud systolic murmur existed over the cardiac region, with hypertrophy of the left ventricle ; the aortic orifice was also much constricted, and the valves were covered with large fibrous vegetations. No. 16, by J. Burney Yeo, M.B., is entitled "Case of Cardiac Tumour in the Cavity of the Left Ventricle." It was found in the body of a man of 27, who died suddenly in the street. He had suffered from attacks of dyspnœa and from faintings. The tumour was one and a-half inches long by one broad, and enclosed, as it were, three of the papillary muscles, and lay so as to cause very considerable mitral obstruction. In structure it would seem it did not agree with any of the usual products of disease. No. 17, by W. S. Grenfield, M.D., is entitled "Stenosis of the Orifices of the Coronary Arteries of the Heart, due to Endarteritis Deformans at the Commencement of the Aorta." It occurred in a woman of 27, whose health was stated to have been tolerable, and who had not had any severe illness. The death was sudden. Disease of the aorta itself had all but closed up the mouths of the coronary arteries. With this state the heart itself, though to the naked eye it looked healthy, was affected with fatty change, which, though slight in degree, was "widely distributed." The age of this person is worth noting, as well as the special features of the morbid changes found. No. 23, by J. F. Goodhart, M.D., is an example of "Spontaneous Cure of Abdominal Aneurism, with Embolism of the Abdominal Aorta." The blocking of the aorta seems to have caused gangrene of the toes. The aneurism was placed close to the cœliac axis, and had caused absorption of two of the bodies of the vertebræ. No. 24, by W. H. Dickinson, M.D., is also "A Case of Abdominal Aneurism compressing the Ureters and Descending Colon, and accompanied by unusual symptoms." Much obscurity hung over the diagnosis of this case, and indeed it is remarkable how many similar cases occur. We ourselves have seen several. In this particular case vomiting and very marked constipation existed, and the patient was brought to death's door by suffering, always referred to the left colon, and spreading downwards from this. The entire look of the patient and disease was that it was malignant. Yet from this state, and having had bed-sores, he recovered for a period of fifteen months, when one day at dinner he was seized with severe pain in left lumbar region and a fainting fit, and shortly afterwards passed a quantity of clotted blood. From this it became evident an aneurism had burst into the bowel. On examination the tumour was found attached to the ureters and colon, and this explained some, but not all the symptoms, which existed during life. The whole case is a very remarkable one. The patient's age, we should have stated, was 76.

(*To be continued.*)

◆

DISEASES OF MODERN LIFE. (*a*)

The publication of a work of this character by so accomplished a physician is a matter for general congratulation. The attractiveness of the subject-matter, and the acknowledged literary skill of the writer, are sufficient guarantees that the book will prove interesting and instructive. The work is well written and the subjects are handled in a vigorous and graceful mannner. In the preface it is written, "The book, medical in all its aspects, is avowedly written for the study of the intelligent public as well as for medical men ;" and it will be in general request amongst its chosen lay as much as medical readers. What betwixt the recent work of Dr. Milner Fothergill and the one before us, the "lay readers" or the "intelligent public" ought to be fairly well instructed as to how to avoid the causes of disease, and so to maintain themselves well in health. That one or more books of this character are desirable may be admitted, and it is scarcely to be wished for that the views of any one writer should too universally obtain ; nevertheless, there is little scope left for other works on this and cognate subjects. Dr. Richardson has described vividly the ailments which are increasing as the

---

(*a*) "Diseases of Modern Life." By. B. W. Richardson, M.D., F.R.S., Honorary Physician to the Royal Literary Fund, &c., &c. Macmillan and Co., 1876. Pp. 512.

consequences of the conditions of modern life. Some might feel inclined to say too vividly. We can scarcely conceive a lay reader perusing the chapter on "Disease from Worry and Mental Strain," without a good many misgivings about himself, and vague fears which will only be allayed by repeated consultations with his physician, and the reiterated assurance that he is sound, and not the subject of severe latent subtle tissue change which is endangering his existence. In this section of the work there is much which reminds one of Winslow's book, "Obscure Diseases of the Mind and Brain," only here the different abnormal sensations indicate rather failure in the heart than in the brain. If the present work proves as profitable to the profession as the one just alluded to, Dr. Richardson will be a species of benefactor to his medical brethren.

In describing the diseases induced by mental strain and physical overwork there is an opportunity offered for displaying those embellishments, which are furnished by an active imagination, and of surrounding the white light of bare fact with a few coloured rays. Indeed, it would be impossible to construct a readable and interesting book without so acting. Nevertheless, we do not say that Dr. Richardson has taken any undue advantage in this way of his opportunities, or that he has exceeded the license fairly permissible. Still to many there would seem a poetic liberty in the following sentence; "In every brain, in fact, there is set up primitively a kingly force, to which all other forces bend. The king may be good or bad, he may be an hereditary king, or a usurper; but he holds the balance; kill the king, and in ninety-nine cases out of the hundred the kingdom is made chaos or dark night." On the other hand, the following sentence recommends itself very clearly to the mind and extorts the admiration: "The man who, after being engaged in business all day, sits down regularly at night to play his rubbers on rubbers, to stake heavily on his games, to bet on his odd tricks, never, I believe, escapes the effects of organic nervous shock. Some of the worst forms of such shock I have seen have sprung from this cause."

Dr. Richardson is peculiar in his way of regarding many things, and often sees with much vividness what is not usually very apparent to others; but, on the other hand, he frequently does not see what is clearly apparent to other people, and his support of Bichat's hypothesis as to the nature of life at the present is an instance of the latter. "We call the force that resists the earth, vital. We say it resists death, we speak of it as stronger in the young than in the old." This method of handling his subject is vigorous, and his arrangement of the various matters of which he treats are distinct. After the diseases produced by mental and physical strain, and from the effects of the passions, he describes the consequences of indulgence in alcohol. With much here written agreement is alone possible, and yet there are points where difference of opinion is unavoidable. We can but admire this statement. "It is assumed by most persons that alcohol gives strength, and we hear feeble persons saying daily that they are being 'kept up by stimulants.' This means actually that they are being kept down; but the sensation they derive from the immediate action of the stimulant deceives them, and leads them to attribute passing good to what, in the large majority of cases, is persistent evil." The diseases which are produced by indulgence in tobacco are made the most of, too much of, indeed; while but one brief chapter is devoted to diseases from narcotics. We are glad to see in it the evils which have sprung from the discovery of chloral hydrate clearly and distinctinctly. "Chloralism" is a disease rapidly growing: and a sad disorder too. After an account of diseases wrought or induced by our food, by the air, by certain occupations, come the diseases due to sloth and idleness, a chapter worth perusal, and then the disease arising from late hours and broken sleep. Dr. Richardson advocates eight or nine hours sleep out of every twenty-four. Less is undesirable, at the present day at least. The whole chapter deserves careful study, and it is impossible to give any idea of it by abstract or extract. The evils resulting from dress follow next, and then disease from moral contagion, followed by a brief chapter on "inter-marriage of disease." The habit of giving a summary of the contents of these popular scientific works is followed here, and in a few pages the reader can go over what he has read in a brief form suited to definite remembrance.

On the whole, the book before us must be approved of, and Dr. Richardson has done good service in its construction. It is a useful book, even if rather sensational in parts, and is pleasant reading. There is much in it which should be read and pondered over by medical men as well as by lay readers, and advice given by which they might profit.

Medical News.

Royal College of Surgeons of England.—The following gentlemen, having passed the required examination for the diploma, were duly admitted Members of the College at meetings of the Court of Examiners on July 27th, 28th, 31st, and August 1st and 2nd:—

Bailey, George S., Launceston, Cornwall.
Blackader, A. D., B.A., M.D., Montreal, Canada.
Bouton, George Charles, L.S.A., Dinan, France.
Brett, John, North Kensington.
Chawner, Alfred, Ryde, Isle of Wight.
Christian, John, Barrow, near Oakham.
Clapp, Robert, Teignmouth.
Clark, Frederick, L.S.A., Fenchurch Street.
Conolly, Paul Bennett, Somerset Terrace.
Cumming, Robert F., Exeter.
Davies, John, L.S.A., Treorky, South Wales.
Duke, Thomas, Kennington-park Road.
Dunn, Hugh Percy, Warkworth.
Dutton, Edward G., L.S.A., Hammersmith.
Evans, William M., Cardiff.
Fell, Thos. K., Ulverstone, Warwickshire.
Gaisford, Martin, Ilfracombe.
Garbutt, J. Gilliott, Prince's Square, Bayswater.
Gay, Charles W. E., L.S.A., St. Albans.
Gibson, William, Middlesboro'-on-Tees.
Gilbert, Hy. Langton, M.D., Sherbrooke, Canada.
Griffiths, Gilbert Saunders, L.S.A., York Street, W.
Gross, Charles, Erith, Kent.
Hare, Evan Herring, Putney.
Harris, Arthur Byam, Wootton-under-Edge.
Heald, Robert, Sleaford, Lincolnshire.
Hindle, George, L.S.A., Over Darwen.
Irving, John C., Dunnington, near Spalding.
James, Joseph Brindley, Hackney Road.
James, Joseph R., Sirhowy, Monmouthshire.
Johnson, George S., Savile Row.
Johnson, Thomas, Birmingham.
Jones, David, Llandysil, North Wales.
Jones, Thomas, Ningpo, China.
Kellie, George I., Dunbar, Haddingtonshire.
Lacey, Chas. W., Langboro', Leicestershire.
Lewis, Daniel G., Merthyr Tydfil.
Low, Frank H., Blackheath.
May, Arthur W., Launceston.
Mears, William Pope, Bromley-by-Bow.
Metcalfe, Peter H., Bungay, Suffolk.
Michell, Henry Slyman, Truro, Cornwall.
Middleton, C. F., Sydney, New South Wales.
Mortimer, John, Exeter.
Moullin, Charles W. M., Porchester Terrace, W.
Nicholson, William R., Burnley, Lancashire.
Norman, Walter, Adelaide, South Australia.
Palmer, L. Harold, Haverfordwest.
Parker, William Herbert, L.S.A., Cheltenham.
Parkinson, Sidney G., L.S.A., Northampton.
Perry, Francis Frederick, Hornsey Road.
Pratt, Walter, Billesdon, Leicestershire.
Price, John, Harrow.
Pye, Walter, Ealing, Middlesex.
Reynolds, Wm. Percy, Norwood Road.
Richardson, T. Arthur, Newport, Pembrokeshire.
Roche, Eugenius A., Sunderland Terrace, W.
Sankey, Herbert R. O., Cheltenham.
Slatter, Oliver Thomas, Chepstow.

Smith, Tom, West Bromwich.
Smith, Ernest S., Stanhope Street, Hyde Park, W.
Snell, Edward A., L.S.A., Richmond, Surrey.
Strover, Walter, L.S.A., Jersey.
Thomas, John R., Llanelly, South Wales.
Todd, John, L.S.A., Blackheath.
Turner, Edward B., Sussex Gardens, Hyde Park, W.
Walker, Hyde E., Walsall, near Birmingham.
Walker, William, L.S.A., Bath.
Webb, John R. W., Fairford, Gloucestershire.
Weiss, Herbert Foveaux, Chester Terrace, S.W.
White, Charles Haydon, Tufnell Park, N.
Whitsea, John, Sutton St. Edmonds.
Williams, Alfred G., Carmarthen.
Wood, Edward Joshua, Higham.

Vital Statistics.—From the Registrar-General's report we learn that during last week 5521 births and 4066 deaths were registered in London and twenty-two other large towns of the United Kingdom. The mortality from all causes was at the average rate of 26 deaths annually in every 1000 persons living. The annual death-rate was 18 per 1000 in Edinburgh, 19 in Dublin, 22 in Glasgow, and 30 in London. The annual rates of mortality during the same period in the other large towns were—Bradford 22, Norwich 26, Brighton 19, Wolverhampton 22, Birmingham 20, Sunderland 26, Portsmouth 24, Sheffield 22, Plymouth 12, Nottingham 26, Liverpool 25, Bristol 27, Leicester 32, Oldham 19, Newcastle-upon-Tyne 24, Hull 26, Manchester 29, Salford 29, and Leeds 34. The annual death-rate from the seven principal zymotic diseases averaged 9·0 per 1000 in these towns, and ranged from 1·0 and 2·2 in Brighton and Plymouth, to 11·6 and 13·2 in Sunderland and Leeds. Scarlet fever continues fatally prevalent in Portsmouth, and small-pox caused 7 deaths in Liverpool and 4 in Manchester and Salford. In the provincial towns referred to 905 deaths were referred to diarrhœa, against numbers increasing steadily from 88 to 669 in the four preceding weeks.

New Act on Poisoning Animals.—By an Act just printed (39 Vict. c. 13) to prevent the administration of poisonous drugs to animals, it is provided that if any person wilfully and unlawfully administers to, or causes to be administered to, or taken by any horse, cattle, or domestic animal, any poisonous or injurious drug or substance, he shall be liable (unless some reasonable cause or excuse be shown on his behalf) on summary conviction to a penalty not exceeding £5, or at the discretion of the Court to imprisonment with or without hard labour, for any term not exceeding one month in the case of a first offence, or three months in the case of a second or subsequent offence. The provision is not to apply to the owner or person acting by his authority, and nothing in the new law is to exempt a person from other punishment, provided he is not punished twice for the same offence. The statute is to be cited as the "Drugging of Animals Act, 1876."

South London School of Materia Medica and Pharmacy.—The following is a list of the pzize-takers at the close of the summer session:—Senior Chemistry (medal) Mr. Amoore; (certificate) Mr. Hicks, Mr. Glegg. Junior Chemistry (medal) Mr. Truman; (certificate) Mr. Widdowson, Mr. Owen. Botany (medal) Mr. Bevan; (certificate) Mr. Evans, Mr. Hart, Mr. Allsworth, Mr. Weston. Materia Medica (medal) Mr. Walker; (certificate) Mr. Amoore, Mr. Collingwood. Pharmacy (medal) Mr. Widdowson; (certificate) Mr. Johnson, Mr. Walker. Practical Dispensing, Mr. Cooper, Mr. Harrington.

Amaurosis through Suppression of Menstruation.

A young woman, twenty-one years of age, labourer, during menstruation, immersed her feet in a small stream, and the sanguinal flow ceased immediately; this occurred on the 30th of July, and soon afterward she experienced a peculiar sensation of pressure in both orbits. On the morning of the 5th of August she had double amaurosis complete. Absolutely nothing was revealed by the ophthalmoscope at the time. The patient complained of intraocular pain, which was notably increased by compressing the globe of the eye. Bathed the feet in mustard water; sinapisms to the hips, argol administered in refractory doses, blood-letting from the temple. On the morning of the 9th, in consequence of an abundant diaphoresis which occurred upon the right half of [illegible]nd an abundance of lachrymal fluid from the right eye, there was a diminution of pain in that eye, and a partial return of luminous impression upon the central field of vision. Having continued the diaphoresis until the 11th, considerable improvement was made in the vision of the left eye, from which, also, came the lachrymal fluid. The following month, notwithstanding the use of emmenagogues, menstruation did not appear, but returned seven weeks from the date of suppression, and with it disappeared all visual troubles.—*La Crónica Oftalmologica.*

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention t this rule.

Reading Cases.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the Medical Press and Circular, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat, after it has passed through the post.

The *Pharmaceutical Journal* never reaches our Irish office until twenty-four hours later than any of its contemporaries which are published on its day of issue. It ought to be possible for the Journal of the Pharmaceutical Society to keep time with its readers as accurately as its competitors.

Dr. J. L.—The matter has not escaped our notice; we are awaiting certain contingencies.

"The Trumpet shall Sound."—An enthusiastic admirer of Miss Victoria Woodhull, who for several years jointly edited Claflin and Woodhull's monthly in America, has just come out with a violent panegyric of his female medical love in the columns of a contemporary. Speaking of the religious trait in her character he says: "Once a sick woman who had been given up by the physicians was put into the care of Miss Woodhull, who attempted to lure her back to life. This zealous woman, unwilling to be baffled, stood over her patient day and night, neither sleeping nor eating or ten days and nights, at the end of which time she was gladdened not only at witnessing the sick woman's recovery, but at finding that her own body, instead of weariness or exhaustion from the double lack of sleep and food, was more fresh and bright than at the beginning. Her face, during this discipline, grew uncommonly fair and ethereal, her flesh wore a look of transparency; and the ordinary earthiness of mortal nature began to disappear from her physical frame and in its place to be supplied with what she fancied were the foretokens of a spiritual body. These phenomena were so vivid to herown consciousness and to the observation of her friends, that she was led to speculate profoundly on the transformation from our mortal to our immortal state, deducing the idea that the time will come when the living human body, instead of ending in death by disease and dissolution in the grave, will be gradually refined away until it is entirely sloughed off, and the soul only, and not the flesh, remains. It is in this way that she fulfills to her darling hope the prophecy that 'The last enemy that shall be destroyed is death.'" Having passed the meridian of life we cannot recall to memory the transparency of our sublime person; but then we were of the opposite gender, and could hardly expect that our external frame and our internal organs should have obtained that glassy appearance at the maiden age of 40, so that our friends could "see through us" ere we were "sloughed off" from the face of this cruel earth, as they appear to have done with our editorial friend some few years later.

Spes.—You will find full particulars and directions in our "Students' Number" of Sept. 22, 1875, by reference to which you will gain more information than we could give you by answering your queries in the order you have put them.

The German Army.—From official sources *The Veterinary Journal* learns that "in 1873 the German army had 693 veterinary surgeons. The number of horses was 94,742, of which 69,161 belonged to the cavalry, 15,163 to the artillery, and 2,274 to the transport. During the Franco-German war the army numbered 1,350,787 men and 263,735 horses. Of this amazing number 936,915 men and 232,393 horses were in the active army, and 413,872 men and 31,337 horses in the reserve."

Americana.—The institution is closed for repairs.

Mr. Parker, M.R.C.S., of Bath, sends us a copy of a post-card he addressed to the Right Hon. W. E. Gladstone in reference to the subject of Medical Education, founded on the address at the London Hospital, upon which we recently commented. We are curious to know the ex-Premier's reply to such an ambiguous question; we have puzzled ourselves to do so, and have given up the attempt. Perhaps the illustrious Statesman addressed has done the same! *Ubi lapsus quid feci, veritas stabits..*

Dr. Williamson.—The journal referred to is excellently conducted, and contains a good deal of valuable information. The editor is Dr. Gubler.

ADDRESS IN MEDICINE. (*a*)

By Edward H. Sieveking, M.D., F.R.C.P.,

Physician Extraordinary to Her Majesty the Queen; Physician in Ordinary to H.R.H. the Prince of Wales; Physician to St. Mary's Hospital, &c.

(*Continued from page* 108.)

The *second event* of modern times, on which I beg your leave to dwell for a brief space, as specially connected, in my estimate, with the advancement of scientific medicine in England, is closely associated with the name of Sir John Forbes; from 1836, when he resided at Chichester, to 1846, when he had long been a denizen of Old Burlington Street, editor of the *British and Foreign Medical Review*, of which it would be difficult to speak too highly, whether we consider its literary merits, its thorough honesty and impartiality, or its grand and cosmopolitan scientific breadth.

The October number of 1846 concluded the editorial labours of Forbes; and in the parting summary which he presents to the reader of his work in connection with the journal, the editor, among other reasons, mentions the diminished sale, which he attributes in part to an article which he had published, and of which he acknowledged himself the author, in the January number of the same year. It is this article to which I venture to assign the maternity of a new era of the medical profession in its scientific position in Her Majesty's dominions. It was entitled "Homœopathy, Allopathy, and Young Physic."

This article was essentially a protest against the polypharmacy of the day, and a summons to the practitioner seriously to consider and studiously to examine the resources and the methods of treatment at his command. It was, without intending to be so, an amplification of the Hippocratic views so ably propounded by our departed friend, Dr. Warburton Begbie, at our last annual assembly, as to the physician's duties in the face of his great enemy—Disease. Though most of the arguments used by Forbes were as old as the hills, his boldness in bringing them forward at this particular time which he selected startled the profession like a thunderclap, and the author was subjected to much animadversion and misrepresentation.

Thirty years have gone by, and I may assume that few among my present audience are familiar with the article in question; or if they are, that they would hesitate to subscribe to most of the doctrines with which Forbes shook the withering tree of routine. Thirty years ago great agitation prevailed in the profession, owing to the warmth with which many members of the upper classes of the community received and supported Hahnemannian tenets and practice; the hostility which the article aroused was due to its being represented by its cavillers as favouring those views. I am not one of those who can subscribe to the ancient doctrine, that in all diseases we find a *vis conservatrix* or *medicatrix*, inherent in the system of the patient, which has simply to be allowed her own way, to lead the patient to a happy release from his malady. There is, according to my observation, no less a *vis destructrix*, (*a*) which has to be met boldly and decisively. But modern English medicine paid too exclusive attention to the latter, while it ignored the former; it placed its trust in the *armamentarium pharmaceuticum* to an extent which we, of the present day, neither follow nor applaud. The trade spirit also had some part in these aberrations; hence it was but natural, as the laity discovered that they might put aside the customary six bottles a day, in addition to the pill at night and the draught in the morning, sent in (and charged for) by the family attendant, without necessarily becoming a unit in the Registrar's death list, that they often attributed a cure, which we know the *vis medicatrix* is capable of effecting in many cases, when aided by a suitable regimen, to an infinitesimal dose of sepia, pulsatilla, or nux.

In an ancient work on medicine, published in 1559, the author, Mr. Bullein, (*b*) introduces two friends, discussing the merits of their physicians; one says, that being very ill,

---

(a) **Read before the British Medical Association at Sheffield.**

(*a*) "Destructrix" is not a Latin word; "conservator" and "conservatrix" are Ciceronian; "destructor" occurs in Tertullian: but although I have no authority for the use of the word "destructrix," I trust it may, from the context, and in accordance with etymological precedent, be considered justifiable.

(*a*) *New Boke of Physic*, by W. Bullein. 1559. **Black letter.**

he had called in three physicians at once, to the astonishment of the other, who fears that his purse would scarcely suffice for the discharge of the customary fee. The reply is, that Doctor Diet, Doctor Quiet, and Dr. Merryman had effected a cure, which had cost the patient nothing in the coin of the realm. These three doctors have never been overlooked with impunity, as some of the most valuable contributions to the literature of the present generation testify. It is, however, not to be denied that, when Forbes's article roused the indignation of his opponents, the elements in treatment which they allegorically represent had given place almost entirely to what was termed heroic methods. Bleeding from the jugular vein and temporal artery, large and repeated doses of mercurial and antimonial preparations, constant venesection and leeching, were in daily use; and it was not to be wondered at, that as physiology and pathology came to be more thoroughly studied, the difficulty of finding a satisfactory reply to an inquiry why these things were done should arrest the thoughtful practitioner. Homœopathy gave him a rude shake, and he found it necessary to unlearn much and to retrace his steps, so as to recover the true path of nature. But it was only on the principle, *fas est et ab hoste doceri.* Forbes made himself the spokesman of many, who, by the support they rendered him, showed that while they recognised this error, they were as far as he was from regarding homœopathy as a development of science. Listen to what he says. After analysing other evidence in favour of homœopathy, he very carefully reviews *An Inquiry into the Homœopathic Practice of Medicine,* by Dr. Henderson, a professor of medicine in the University of Edinburgh, who had become a convert to Hahnemannian doctrine; Forbes remarks upon the cases he reports, and the deductions he adopts: "Men capable of admitting cases of this kind as evidence, and we could extract fifty from Dr. Henderson's book much feebler than this, are demonstrably disqualified to treat of things which demand for their handling the stern logic of a masculine mind." Forbes sums up the results of his entire inquiry into the value of homœopathy in the following words: "If, for the sake of argument, we were to admit that homœopathy were partially true, and therefore that it might fairly be received as one of the recognised methods of treating disease, it would appear to us, according to our present light, to be very unfortunate if this were done. The guiding principles of homœopathy appear to us to be of that character which must render its exercise very injurious to medicine as a branch of science. Based as it is on mere extrinsic secondary phenomena or symptoms, and exclusively engaged in the search for and adaptation of specific remedies to such phenomena, we cannot but regard it as calculated to destroy all scientific progress in medicine, and to degrade the minds of those who practise it. Its direct tendency seems to be that of severing medicine from the sciences and establishing it as a mere art, and thus converting physicians from philosophers to artisans. Of course if, by such a conversion, diseases were to be better treated, and more speedily and frequently cured, it would not only be absurd, but transcendently wicked so to sacrifice the welfare of humanity for the sake of a scientific phantom; but, as we have said, it is anything but proved that such a result would follow the change, and therefore, until the proof is obtained, it behoves all who regard the prosperity and dignity of true art to resist its progress."

The writer further examines the causes of the success which homœopathy enjoyed in his day, and gives numerous interesting and striking illustrations, which lead him to the conclusion "that the curative powers of Nature suffice to explain all the triumphs of homœopathy." He then adduces some o the influences which we, at the present day, certainly do not regard as in any way the special property of the system, and to which Forbes thought they might be fairly ascribed; they are essentially those which Mr. Bullein more than three hundred years ago summarised in the short allegory above recounted.

I have not the slightest desire to revive the controversy on homœopathy, but the preceding remarks and quotations seemed necessary to bring before you an important phase in modern medicine, and from the slight indications that the [illegible] and place permit me to give, to ask you to realise the strides that the last three decennia have effected in the diffusion of scientific views among the great body of British practitioners. We are approaching so near our own time in the consideration of these matters that it would be invidious to go into further detail. Many of the great workers in the various fields of observation who achieved the present results are still among us, and if I mention one or two subjects of inquiry which pertinently indicate the progress that has been made, it is rather by way of illustration and example than because it is possible to exhaust a subject which might fruitfully occupy entire volumes.

Consider the vague manner in which formerly the influence of air and water was treated—the cosmic, telluric, and atmospheric agencies that were accused of affecting man, without any precision greater than that belonging to dreamland. Consider, on the other hand, the rigid investigations that have engaged scientific physicians from the days of Snow (whom Dr. Wilson designated in his Harveian oration before the College of Physicians as "*Nix per æthera notus,*" but whose claim to the gratitude of posterity rests much more on his inquiries into the origin of cholera in contaminated water than upon his connection with anæsthetics); consider the investigations into the causation of disease by impure water, and the brilliant results that have been achieved as regards the influence of that first necessary of life in the origin and propagation of morbid processes; ponder upon the equally important, though, as yet, perhaps, not equally decisive investigations, that have been made in regard to the aerial germs of disease, the invaluable aid afforded to precise knowledge of morbid processes by microscope and thermometer (instruments unknown to the student of my day)—the searching examinations into the operation of medicinal agents; the revelations of the various sources of disease from food contamination and adulteration; and say whether medicine in its totality does not fully deserve the title of a science, and has not already reaped rewards scarcely recognised by the younger generation of medical men, and certainly not appreciated as they deserve by our non-medical contemporaries; rewards such as Forbes and his coadjutors looked for when they challenged their contemporaries to a more reasonable inquiry into the nature and history of disease, and the real value of the various agents at our command for its removal.

And, for practical results to the community at large, look at the increased duration of life wherever the medical man has been listened to; to the enormously increased value of life in the army (in connection with which question allow me to advert to the loss the nation has but just sustained in the death of that great man, our associate, Edmund Parkes); to the general reduction of the death-rate; the check put upon the inroads of disease in many noxious trades and occupations; the reduction, nay, almost arrest of mortality in some diseases that, under "heroic" treatment, more frequently succumbed than recovered—diseases of the head, of the chest, of the abdominal viscera. May we not quote the remarkable revelations with regard to trichiniasis and other parasites as permanent victories? Is it too early yet to speak of what some of us may regard as a victory over the bane of England's youth and early manhood, rheumatic fever, by salicylic acid? Look at the advances of surgery in regard to its conservative labours, its anæsthetics, its antiseptic treatment! Who that scans the changes in medical training and conduct during the last thirty years can deny that mankind is the better for the more scientific development of medicine, and that the more we encourage true scientific work, the grander will be the beneficial results that we and our descendants may reckon upon.

But while we rejoice over our reminiscences, we must not forget that every step in advance opens out to us a new vista of further and higher responsibilities. Many of the inquiries that have been initiated have not yet been terminated; many results attained by the man of science have not yet found their practical application in daily life. An association can do little directly to promote science. Scientific work is rarely well done by large assemblies. The student works in the quiet laboratory, in the secluded library, or at the bedside of his patient, and though he may be encouraged by the sympathy and approval of his contemporaries, science and its results are, and ever will be, his chief rewards. But it is our duty as an association to assist in rendering his results, if not beneficial to the inquirer, at least to his fellow-men, and preventing impediments from being put in his way, that thwart his undertaking, damp his zeal, and enfeeble his powers by the chilling effect of neglect and discouragement. In this direction our association has already done much. We cannot create the *sollers ingenium,* but we may smooth the difficulties in its path, and assist in securing its recognition by those less competent to judge, and yet willing to benefit by its activity.

It appears to me especially the function of an association like ours to spread the knowledge of scientific results, and to secure their application to society. No true work is barren, but it often remains hidden, because its seed falls on uncongenial soil; and it is our part to see that the particular work of the philosophic physician is duly appreciated by those who rule our commonwealth, partly because we are bound to show our gratitude to the benefactors of our race, and partly because the general public are by no means educated in such a direction as to enable them to appreciate the advantages conferred by medical science. Hence, again, I say that the British Medical Association, if it wishes to deserve well of mankind, is bound to exert itself to secure a more public recognition by the State of the aims of the profession, and to obtain for those calculated to represent them properly a more fitting method of realising them than is at present possible. The recognition of state medicine to a claim for university honours is already a step in the right direction, and shows that some of the educated classes are beginning to appreciate the importance of the questions at issue; but how much yet remains to be done is shown by the apathy, of which we forbear to adduce special instances, evinced so frequently by municipal and other legislative bodies in regard to measures of vital importance to their own welfare and that of those around them. Here I hold that our Association has a great sphere of action before it, and what we are able to do in this direction must, if my views are just, be mainly realised by the influence we are able to exert on education in schools and universities.

These observations bring me to the consideration of the *third element* in the modern development of our profession, or our relations to education, to which I crave your indulgent attention yet a little while.

Nearly a quarter of a century ago the poor Welsh apothecary, as he was wont facetiously to denominate himself, and to whom all honour is due, conceived the idea of founding an institution which should, besides providing a home for the invalided and impoverished members of the profession, supply a liberal education, at the lowest possible cost compatible with its scope, for the sons of medical men, many of whom were, as foundation scholars, to receive their training free of all cost. The proposition was warmly received and well supported, so that we may now, in 1876, speak of large and beneficial results. The feeling that animated the supporters of Mr. Propert was doubtless, in the first instance, one of Christian benevolence; but it was also largely based on the desire, now becoming more and more urgent, to give expression to the sense of unity and co-operation pervading the entire profession of medicine. Of course there were some who found fault, and who would have preferred that less money should have been spent upon bricks and morter; but I much doubt whether any scheme would have commanded similar success that had not been accompanied by the conspicuous and tangible product of such a group of buildings as now adorns the heights to the south of Epsom. The eleemosynary character of the institution has been extended, and its typical feature as a centre of professional harmony has insensibly acquired a firmer hold upon the medical public; but it is now gradually achieving for itself a position in the educational institutions of the country which I apprehend will effect a more wide-spread influence than even its sanguine founder anticipated. And it is right that it should do so.

If we look around at the system of education still prevailing in our country to a large extent, can we admit that it accords with the spirit of the times? and do we not rather find that even now the rules that regulated the Trivium and Quadrivium of the Middle Ages hold good to an extent that would seem incredible in a day of railways, electric telegraphs, and penny postage, were the fact not too patent? The bed of Procrustes is still too much the type of modern education. The mind of our youth, whatever its tendencies or aspirations, is still uniformly sought to be moulded upon one monastic system. The glories of Homer, Demosthenes, Horace, or Tacitus, are still forced upon minds incapable of appreciating them, or are made a preparation for a life in which Nature and Nature's laws, a knowledge of mankind in his various relations to internal and outward circumstances, is the first desideratum. No one is more convinced than I am of the value of a knowledge of the literary and social work of the great nations of antiquity; but the question that I would submit to your careful consideration is not how great their value, but how much the manner in which these subjects are taught, and the time that is bestowed upon them when the youthful energies should be trained for the work of life, has interfered with our progress as a nation. Under our prevailing system the highest power that we are endowed with—that of observation and comparison—is forcibly kept down; and even the first requisite of a liberal education, the knowledge of our own language and its marvellous achievements, the power of using and enjoying it to the utmost, is deadened instead of being quickened. At the Epsom College, as is right in an institution which is ruled by medical men, it is sought, so far as is compatible with the requirements of other scholastic bodies, to set an example in giving prominence to the teaching of natural science; and the results, small perhaps as yet, are already giving promise of a greater future, and cannot fail to make a wider impress upon our national system of education.

But is it right that we should wait for the slow progress which our small institution may make in public estimation, without taking further steps to secure what, in and out of our profession, is almost universally admitted to be a desirable or necessary object? Can we not do something to secure better education at large, and a more general adoption of principles which we believe to be irrefragable? It would be useless to put such a question if I saw no remedy; but I believe the remedy is at hand, and that it largely depends upon the medical profession, though it is not their immediate function to occupy themselves with educational matters, to cause a gradual and peaceful revolution in the prevailing system.

To do so, however, we must go, not so much to the primary schools, as to those fountain-heads of English education, which put the stamp and die upon what they regard as success, and thus compel all dependent upon their fiat to work as they list. It would be quite impossible now to discuss the history and growth of our universities; but we, as Englishmen, can scarcely admit that they do now, or ever have, taken that position as teachers of the great body of the nation which we see aspired to or occupied by continental universities. An university should be, as its name denotes, an *universitas literarum*, and not limit its teaching to one or two disciplines, which though valuable in themselves, are simply means, not always appropriate, to an end to be attained elsewhere. To my apprehension, an university does not deserve the name, which does not within itself teach the principles and theory of all science, and which adopts a *régime* and habits that exclude from its precincts all whose mental calibre cannot adapt itself to one formula of a classical or mathematical shibboleth, or whose means compel them to enter a professional calling without unnecessary delay. I maintain that *all* members of learned professions ought to enjoy an university training, and that a country whose universities do not allow of their students acquiring the entire theoretic part of their respective professions within their walls, neglect the first duty for which they were called into existence. I will not now speak of any other profession than our own; but, as regards medicine, I conceive that many of the educational difficulties that have been so long under discussion, and that are far from being removed, will disappear when such arrangements are made at our universities that the great body of practitioners can avail themselves of their advantages. In order that this may be possible, it is necessary that a standard of preliminary training be fixed which shall qualify for admission into the university, and that, at the age of eighteen or nineteen, when young men generally put on the cap and gown, they should be permitted to pass at once from the subjects they have been learning at school to those professional studies which the universities ought to be able to teach infinitely better than the small, self-supporting academies of medicine now scattered over the country.

It is no small credit to the energy of the medical schools as they exist, that they have done as much as they have done; but, with the increase of knowledge and the demand made upon the lecturers, it is simply impossible that the latter should keep pace with the times, unless they are exempted from the *res angusta domi*, and are enabled to devote themselves entirely to science. At present, the majority of lectureships are treated simply as stepping-stones to medical practice, and hospital physicians and surgeons pass from one subject to another, not so much by virtue of special qualification, as by the all-powerful influence of professional seniority. Something may doubtless be said in favour of our present system of competition; but I would ask whether the balance of argument is not in favour of professorships at our ancient universities, where the increased numbers of alumni would render a professorship not only a place of high and laudable ambition, but would make its emoluments worthy of acceptance by those of our body who desire to devote themselves to, and merge themselves entirely in, scientific research. Botany, chemistry, natural philosophy, physiology, anatomy, comparative anatomy, pharmacy, and materia medica, the theory of medicine and surgery—might all be better and more profitably taught at an university than in provincial or metropolitan schools of medicine. The numbers that would flock to our universities if they held out such advantages would render necessary the endowment of more than one professorship for each discipline, and thus a salutary rivalry, without which stagnation would ensue, would be preserved. And if our present university arrangements are insufficient to provide for the two thousand medical students who annually inscribe their names on the registers of our schools, what is there to prevent the establishment of more universities in towns willing to advance the growth of the sciences, and possessed of fewer of those sanitary defects which mar the beauties of Oxford and Cambridge?

It is utterly against my views that an university should belong to a class; and therefore, while I maintain that we physicians and surgeons of England may legitimately labour for the foundation of a new university, which shall embody certain methods and principles, if the older institutions cannot receive us, I should regard the attempt as futile, unless provision were made at once to establish professorships required by all the faculties, so as to ensure an influx of ingenuous youth, destined for all the various walks of life. Has Germany suffered either by the poverty or the number of its universities? Has that great country not ever been to us a model, both in the manner of teaching and in the achievements of the taught?

I value political independence, honour, and integrity even higher than scientific growth; but, as the former are secured to us, as far as institutions can make them sure, is it not time that we throw some of our superfluous energies into the cultivation and development of the scientific growth of the nation, and emulate our cousins on the other side of the German Ocean in the number and power of our universities, as they are essaying to walk in that path of constitutional freedom which has so long been the Briton's birthright? It is not found in Germany that the transition of a student from one university to another either interrupts his studies or checks his professional career. There is a sufficient understanding among these bodies to allow the thread that was broken at one to be taken up at another, the attendance at one admitting to its equivalent position at the other. The benefits that I would thus confer on medical students would react most beneficially upon the community. Students of medicine would enjoy the advantage of the highest teaching intellect that could be commanded, and they would benefit by that free interchange of thought and opinion which is the characteristic feature of the intercourse at an university between young men treading the different paths of life; they would feel themselves to be, more than they now are, an integral part of the republic of letters, of which an university ought to be the type. But I question whether the gain to the nation would not be even greater than that conferred upon the medical student; for, indirectly, the members of the legal and clerical professions, and that large number of the gentry who visit the universities rather for the purposes of general education than with the view to following a profession in after-life, would of necessity interchange opinions with their medical colleagues, and imperceptibly become imbued with a respect for, and a knowledge of, nature and nature's laws, which could not but favourably react upon their execution of future duties.

The gulf that even now in England separates the inquirer into God's laws in Nature from his "educated" fellow citizen, could not be more distinctly shown than has been done by the recent discussions on vivisection, in which the non-medical community have thought it right and honest to hurl at us all the opprobria of language from an entire misapprehension of the means, the scope, and object of our researches. Our legislators would rival the enemies of Galileo; if their views had been in the ascendant when Harvey's discoveries were made, we might still be running after the will-o'-the-wisp of an Archæus; and if our detractors had their way the progress of science and humanity might even now receive a check that would retard the advancement of civilisation. What but a free interchange of thought and opinion between the most educated of the rising generation can prevent the recurrence of similar bathos.

One of the great obstacles to the diffusion of sanitary knowledge, and of a due appreciation of the unselfish labours of physicians, consists in the ignorance which still prevails so largely, even among the higher classes, as to their object and scope. The free intercourse of young men of different professions would do much to remove existing prejudices, and to widen the actual amount of knowledge, so that their cooperation in after-life would be more certain and effective, from the community of feeling and interest created in them by early association.

The practical question remains, whether our present social constitution admits of the realisation of a plan like that suggested. Does it not resolve itself mainly into one of pecuniary means? The greater demands now made by our examining boards appear to answer this in one direction, while the success attending the establishment of a college like Keeble College seems to answer it in another. The present extravagant cost of a residence at Oxford and Cambridge, which elicits the groans of many a *paterfamilias*, is shown not to be a necessity; if it were unavoidable, it would be an argument against the admission of the bulk of medical students to the universities which would silence me. There are many who value their university residence rather because it is a proof of their parents having been wealthy than because they have any superior acquirements to boast of; but I do not think so meanly of the ruling powers as to believe that they would desire to make property the qualification of primary consideration in the test of admission. The heartiness with which the universities have, during the last twenty years, thrown themselves into the great question of educational reform, and given material aid to its intrinsic development, is the best proof that they recognise their high mission. At the same time, it may be doubted whether their energies in directing middle-class examination are not somewhat misplaced. We all know one or more benevolent ladies whose labours for the clothing clubs, soup-kitchens, visiting and missionary societies of their parishes, are unlimited, but whose children are allowed to run wild from want of that home-supervision which their mother's expansive benevolence prevents her from exercising.

Does not *Alma Mater* also tend, with due reverence be it said, to a partial neglect of those duties which lie nearer home in order that she may acquire the name of an universal foster-mother? At all events, if she has spare energies for the chickens that are wandering about untended and uncared for, she ought, surely, first to show that her own brood has received the necessary food and protection, and that she has guarded them from becoming the prey of the designing and watchful fox.

Whether our Association can take active steps towards the consummation of what I would fain hope many of my hearers may consider to be a desirable object is a question that I dare not now dwell upon at large, but I entreat your permission to add a few more words on the subject. I apprehend we have in the first instance to consider, not so much whether it is possible for Oxford or Cambridge to receive our students, as to determine whether it is right and proper that the future generation of medical men shall receive their scientific training at an university or not. If the affirmative be adopted we may then make our wishes respectfully known to the authorities of the old universities. If they read the signs of the times with our interpretation, we should do well to benefit by the *prestige* of their ancient names, and it would be a matter of rejoicing that those seats of learning would secure the advantages which it is believed would accrue to them. The alternative of a new foundation in a southern or northern county town would still remain. For my own part, I venture to think that, if you endorse the views I have offered you, we should more speedily gain our ends if this great Association resolved that a new university, in which the professorial element shall be paramount, is necessary, and proceeded to take such steps as prudent foresight may suggest to secure the realisation of so great an end.

If I have succeeded in obtaining your sympathies, I have little doubt that the ways and means will be forthcoming to enable us to meet what I regard as the summons of the spirit of progress and science, addressed to ourselves and our contemporaries. If you differ from me, I crave your pardon for having taken up your time unnecessarily; but I should scarcely have been true to myself if I had not seized an opportunity, such as the indulgent offer of your Council has given me to-day, of placing before you a summary of the great work that our Association has done, and the still higher objects that I believe it to be destined to achieve. *Salvavi animam meam.*

When I was first invited to deliver this address, I was told that I should meet you at one of the most frequented health-resorts of England, and I naturally asked myself whether I might not appropriately select some topic of general medical interest connected with hygiene, climatology, or balneology, to enlarge upon; but on review of the past history of our Association and of its influence on our common profession, I could not resist the temptation to take a larger scope, and to ask you whether we are to rest satisfied with what our predecessors have done for us, or whether we should not rather emulate their great endeavours, and seek to place medicine on a higher social, political, and scientific platform. Sloth and stagnation are not to be thought of here, in the very centre of England's manufacturing greatness. Everything that surrounds challenges us with the watchword, "Excelsior!" Modern life is a continuous and hard-fought battle of the intellect. Muscular Christianity is necessary to sustain and invigorate the body; but the training requisite to sustain the mind at its highest point of development is surely now more than ever a question of national importance. The workers in brass and iron, no less than the practitioners of medicine, are indebted to science for their greatest achievements.

What say you? Is it possible for the British Medical Association to do more than has yet been done to place science on a footing worthy of an empire upon which the sun never sets? Can this very meeting take steps to inaugurate a new university in which none shall enter but those who, being well prepared for its curriculum, shall be capable of receiving a training by the highest intellects of the country for even higher work in all that adorns and elevates life?

I cannot hope to carry all your suffrages with me; but, however our views may differ, I am satisfied that we all agree in our reverence for the great names of the past, and in our desire to tread in the footsteps of those who have led us to the position we now occupy.

That we may more and more be enabled to work with and for the growth—physical and intellectual—of our fellowmen, that we and our children's children may become more and more identified with our country's greatness, has been the wish that has prompted the thoughts which thus imperfectly and fragmentarily I have ventured to lay before you, the Members of the Medical Association.

◆

ADDRESS IN SURGERY.

By W. F. Favell, M.R.C.S. Eng.,

Surgeon to the Infirmary, Sheffield.

Mr. President and Gentlemen,—In the first place, allow me to thank the members of the British Medical Association, and particularly those members who are my fellow-townsmen, for the high honour they have conferred upon me in putting this address into my hands; at the same time, when I consider how many amongst the wisest and most eminent of British surgeons have delivered this address in surgery before me, I feel how little anything I can say can rival the memorable utterances of by-gone years, and how much I need (what I know I shall get), viz., the indulgent hearing of the distinguished company here to-day.

If I can tell you nothing *new* to attract your attention or excite your admiration, I hope I may be able to say something useful, and, at all events, to draw attention to facts which will bear investigation again and again. Bearing in mind the rapid advances made in surgery within the last few years, and bearing in mind also the constant changes in surgical practice, it has appeared to me that it is well sometimes, on an occasion like the present, to pass in review some few of the most important changes in practice, comparing them, as far as we can, with recorded results of past experience.

Alterations are by no means necessarily improvements; and, in this age of rapid progress, are we not sometimes in danger of setting too light a value on the things of the past, and of too utterly discarding some remedial measures to which our predecessors attached immense importance? Permit me, in illustration, to quote the words of one of the wisest and most eloquent of surgeons, Sir James Paget. In a very charming and graceful paper, read at the opening of the Section of Surgery at Norwich two years ago, Sir James, referring to his note-book of cases recorded forty years previously, says: "I found there some things which make me still fear, lest in our progress we should have let fall some things which we had better have held, and are now regarding some things too lightly that then seemed very grave, and, perhaps, are so still. For, among the records which I found, are records of methods of practice now almost completely disused, and yet in which I feel confident there was much right. I find, for example, a large and almost uniform practice of bleeding for all acute diseases, for many chronic, for most of those which were unknown and uncertain, and for a large proportion of those in which there seemed to be nothing the matter. Trying to learn something from these things, I come to one or two conclusions, which I am sure the younger members of the profession need to have much impressed upon them. One of them is, that at the *present day we undoubtedly overvalue the blood, and estimate too cautiously the loss of it.*"

Gentlemen, these suggestive words from so profound a thinker and a man of such matured experience are worth pondering over; and may we not meet with many parallel cases in surgery? I know of no class of cases more important, more interesting, and in which more marked change of treatment has taken place within a number of years, than cases of fracture of the skull, and I think no records can offer a more marked illustration of this latter fact than the records of some of the master minds in surgery who have been connected with the hospital I specially venerate, St. Bartholomew's. Permit me briefly to quote the opinion of three men following each other in rapid succession, Pott, Abernethy, and Lawrence.

In Pott's "Surgery," published in 1808 by Sir James Earle, we find that the use of the trephine in almost all fractures of the skull, whether simple or compound, is strongly insisted upon. He says, speaking generally of these fractures: "The number of cases of this kind which are necessarily brought into a large hospital, so situated as St. Bartholomew's, in the midst of a populous city, where all kinds of hazardous labour are carried on, has enabled me to make many observations upon them; and, although I have now and then seen some of them do well without the use of the trephine, yet the much greater number whom I have seen perish with collections of matter within the cranium, who have not been perforated, and for whom there is no other relief in art or nature, has, I must acknowledge, rendered me so very cautious and diffident that, although I will not say that I would always and invariably perform the operation in every case of simple fracture, yet the case must be peculiarly circumstanced, the prospect much fairer than it most frequently is, and my prognosis delivered in the most guarded apprehensive manner when I omit it."

And, again, he expresses his strong opinion, "that enlarging the opening of a fracture by means of a trephine will not produce or occasion much risk or hazard additional to what must be occasioned by the fracture itself that has already let in air upon the membrane; and, therefore, that *that* consideration is, at all events, in some degree at an end;" and so he goes on to argue that, as a matter of *prevention*, operation ought to be had recourse to in nearly all simple or compound fractures of the skull. Moreover, he did not confine his operation to one perforation of the skull, but occasionally trephined in two or three places, so as to embrace the whole of a fracture in the parts so removed; and yet I find, in spite of treatment so heroic, not a few successful cases recorded in his work on "Surgery."

Abernethy differed in his practice from the course insisted on by Pott. He observed that a slight pressure from depressed bone did not interfere with the proper discharge of brain-function; and, whilst admitting that the pressure so exercised might in some cases set up irritation at a future time, he thought that generally the parts beneath became accustomed to it, and no evil results followed, and he thus cautiously expresses his view of the treatment to be pursued. "From all I have learned from books, as well as from the observations I have made in practice and from reasoning upon the subject, I am disposed to join in opinion with those surgeons who are against trephining in *slight* depressions of the skull, or small extravasations on the dura mater."

Lawrence held, perhaps, a more decided opinion than Abernethy, he being certainly opposed to interference in cases of fractured skull, except where symptoms or other conditions clearly indicated it. In an able article on Cases of Injury to the Head, by Mr. Evans of the Hull Infirmary, published in the third volume of "St. Bartholomew's Hospital Reports," Mr. Evans says: "I well remember some years ago the late Sir William Lawrence saying, in the wards of St. Bartholomew's Hospital, where a case had been recently trephined by one of his colleagues, that his experience of forty years in the wards of that hospital was, that such injuries did as well without operation as with it."

Here, then, I have briefly epitomised the opinions of three representative men of one of our great surgical schools, men whose opportunities for observation were immense, and who brought giant minds to bear upon the question; and I could considerably multiply opinions both in favour of and against interference in cases of depressed fracture of the skull, expressed by the leading surgeons of their time. And, though I think I may assert that the balance of opinion is now in favour of interfering extremely rarely in such cases, except where marked symptoms develope themselves, and that certainly a great change in practice has taken place since the teachings of Pott; still, with all the light of past experience to guide us, and with all the recorded results of the practice of the great men of former years for our instruction, the propriety of immediate operation in cases of depressed compound fracture of the skull is still an undecided point in surgery. All authorities agree that, when symptoms of brain-pressure arise as a consequence of such injury, or where inflammatory symptoms develope themselves, not speedily yielding to antiphlogistic treatment, our duty is then to operate by trephining, or using Hey's saw or bone-forceps where practicable, so as to give exit to pus, or remove a source of otherwise fatal irritation; but it seems to me that the important and yet undecided question is, Are we to use these means *at first*, without waiting for the development of symptoms, in order to *prevent* their occurrence? Does the subject of a compound depressed or comminuted fracture of the skull run a greater risk by being trephined at once, though no symptoms exist, or by being left alone?

Two of the most eminent of living authorities strongly advocate immediate interference; you will almost anticipate me when I mention Mr. Prescott Hewett and Mr. Erichsen.

Mr. Hewett distinctly says that, "in cases of compound depressed fracture of the skull, the rule is to operate, and at once;" and Mr. Erichsen speaks even more emphatically. In his very admirable book on "Surgery," he makes the following remarks on the subject:—"So far as my own experience is concerned, which is necessarily drawn purely from civil practice, I can say that, with the exception above referred to, I do not recollect ever having seen a case recover in which a compound depressed fracture of the skull occurring in an adult had been left without operation; but I have, on the other hand, seen several instances of recovery in which the bone had been elevated and fragments removed. The sooner this is done, the better; danger does not arise from early operation, but from delay; the presence of depressed and spiculated fragments pressing into the dura mater must infallibly and speedily induce encephalitis. I have several times triphined under such circumstances as these with success, and have never had occasion to regret doing so. Indeed, there is no class of cases in which the operation of trephining is attended by such successful results as in those of depressed and comminuted fracture." To what circumstances, then, are we to attribute this diversity of practice amongst men so thoughtful and so well able to form opinions? Possibly the excessive use, I suppose I may say the abuse, of the trephine in former times has been one cause of its almost absolute disuse by British surgeons within late years. I think that, in the case of many powerful and active remedial measures, once highly esteemed and strenuously enforced, as extended observation and scientific research prove to us that their employment is frequently unnecessary and often harmful, we are too apt to rush into the other extreme and altogether discard them, overlooking the value of their cautious and carefully considered employment. Another reason, I think, may be the unfortunate results which statistics give in cases where the trephine has been employed; but here, again, if we carefully investigate the existing conditions in many such cases, we must conclude that the same results would have followed, in spite of any treatment. The rule of practice with many eminent surgeons is to have recourse to the trephine *at once* in the treatment of compound depressed fracture, *only* in such cases as are accompanied by symptoms of brain-compression, and rarely, I fear, with a fortunate result; and, although in loose statistics such cases go to swell the number of deaths recorded after trephining, has the operation itself anything to do with the fatal result?

I think that if we come to examine such cases after death, we should almost invariably find some serious brain-lesion which could hardly have terminated otherwise than fatally whatever treatment we had adopted. Permit me on this point to again quote Mr. Prescott Hewett. "It has never fallen to my lot," says he, "to meet with a single case of cerebral disturbance of a formidable or urgent character, in which such symptoms were wholly dependent upon depressed bone. In every case which I have seen with these symptoms strongly marked, there was also some extensive extravasation of blood, or some serious lesion of the brain-substance itself."

(*To be continued.*)

◆

ON THE USE OF SULPHIDE OF CALCIUM IN THE TREATMENT OF SCABIES, AND ON WORKHOUSE SKIN DISEASES.

By Thomas M. Dolan, L.R.C.P.E., L.R.C.S.E., &c.,
Medical Officer Halifax Union, Infirmary, and Halifax Fever Hospital, Yorkshire.

An experience of seven years with over 700 cases of pure scabies has convinced me of the efficacy of the solution of sulphide of calcium in the treatment of scabies, and the satisfactory results obtained by its use induced me to introduce it to the notice of your readers.

It has the merits of being cleaner, easier of application than the greasy substances usually applied, and if properly used results in a certain cure within a brief period.

It is made, as its name implies, from lime and sulphur; the following formula, from many others, may be used:—

Flower of sulphur ...	100 parts.
Quicklime	200 „
Water	1000 „

Boil the whole for some time, allow the liquid to cool, and decant into hermetically-corked bottles.

It is sold by chemists in the form of a bright yellow solution, and hence is popularly called golden lotion.

Before applying it my patients are ordered a warm bath, so as to cleanse the body and excite healthy skin action; they are then painted with the solution and placed in bed in blankets.

Next morning they present a peculiar appearance, as, owing to the deposit of the sulphur, they are the colour of a guinea. The beneficial results are soon manifest. The itching ceases, the *vesicles* shrivel up, and after another warm bath the patient may be discharged cured.

The over-use of this remedy causes troublesome irritation of the skin, and is often a source of anxiety and trouble until the cause of it is known. It should be at once stopped, the patient bathed in soda and water, when all ill effects will speedily disappear.

It has also the property of destroying anything of a fungoid growth.

When we have itch of long standing in irritable, badly-nourished, strumous subjects, other treatment has necessarily to be adopted to remedy the complications.

There is a sulphide of calcium in powder of which I obtained a specimen from Burgoyne, Burbridges, and Co., London, but it has not the same happy influence as the liquid I have been in the habit of using. There is also a bisulphide in the form of a clear colourless fluid of pungent odour, which is very irritating when applied to the skin. It has no effect in destroying the *acari*, and produces when used an unpleasant erythematous rash.

The clothes of the patients must also be submitted to disinfection, which may be done by placing them in the old sulphur-stove, or by submitting them to heat in some such apparatus as Nelson's patent, whereby the *acarus*, and its eggs are destroyed without injuring the garments. This remedy recommends itself to workhouse medical officers (who have, unfortunately, a large percentage of itch patients) on the ground of economy.

Recruited as are the inmates of our industrial schools and workhouses from tht lowest strata of society, the medical officers of these institutions have but too often to contend with disease resulting from impaired nutrition and hereditary taint, and their skill and patience taxed in arresting at one time it may be the curse of large schools, *ophthalmia*, or at another the invasion of skin disease of a virulent and persistent form.

Having had two epidemics of skin disease amongst the children under my care, the results of my experience may prove useful to some of my younger *confrères*.

The difficulties to be experienced in eradicating an outbreak are very great. The classification of the form of disease is oftentimes a source of trouble, for it presents itself under so many forms of pustules, papules, vesicles, &c., that it cannot be assigned to any of the recognised forms as laid down in our text-books, but must be treated on general principles, always remembering that we have to deal with constitutions lowered by bad diet, specific disease, and that the general health must be improved before topical treatment will be of any avail. Isolation is oftentimes not easy of attainment. Insufficiency of accommodation, want of proper and intelligent nurses, deficient water supply, separation of towels, caps, brushes prevent the medical officer from so speedily effecting a cure as he would be certain to do with patients placed under more favourable circumstances.

Both the epidemics that came under my notice presented very analogous features in invasion, persistence, and decline; they occurred about the same period of the year, spread rapidly, were tedious in curing, were characterised by similar symptoms, and treated on similar principles.

Several medical friends saw the children with me, and were puzzled to give the disease a specific name, though all agreed that the treatment should be constitutional.

In the last epidemic of 1874 I had the benefit of the advice and assistance of Dr. Moual, Medical Inspector under the Local Government Board, who saw the children when they were nearly convalescent.

His opinion was that the disease originated from a vitiated state of the atmosphere of the schools, and that it depended on the presence of some cryptogam.

The first essential thing to do was to obtain perfect isolation, and this was done at once; the children were transferred to well-ventilated and commodious wards, and each placed in separate beds, their clothes were at once taken from them and thoroughly disinfected, each child being well provided with two towels.

In order that if the *acarus scabei* was present and causing mischief it might be at once destroyed, a warm bath with soda was ordered and the solution of sulphide of calcium applied.

The bathing of children is one of great difficulty, as not more than two children should use the same water, and unless the bathing accommodation is ample it is hard to obtain sufficient supply of hot and cold water, and it is also no easy matter to get nurses to bathe them separately.

This was one of my great difficulties, though I afterwards overcame it by substituting a hose and jet with hot and cold water graduated, so that each child was *douched* in clean fresh-aired water.

The action of the sulphide of calcium upon the children had no beneficial effect, thus satisfactorily proving to my mind that I had not to deal with complicated scabies.

The treatment I adopted was directed to the improvement of the general health, of better diet, beer, green vegetables, &c., and by removing them for exercise in the fresh air away from the poor-house. Medicine of an alterative nature was given, with syrup of the iodide of iron, and syrup phosphate of iron in some cases; whilst in others, where I knew there was a constitutional taint, I administered small doses of iodide of potassium and sarsaparilla.

A few of the children presented an eczematous appearance, and these had to be confined to bed, poulticed with bread and water, and emollient applications applied.

Another difficulty is experienced in the giving and making up of medicines for a large number of children. I had to arrange the doses according to the different ages, and it was no little trouble to the nurses giving the medicine at regular times.

The system of douching with the apparatus I have previously mentioned was regularly continued, and glycerine soap substituted for that ordinarily used. Carbolic soap had been previously very much employed, but I find that the persistent application of it gave rise to roughness of the skin and to desquamation of the cuticle.

Under the above general principles of treatment a gradual change took place in my patients, and with pleasure I was able to send back to their school duties each week a batch of eight or nine until the whole were perfectly restored to health.

Bad heads are oftentimes another source of trouble to the poor house medical officer, generally arising from neglect and want of cleanliness.

Girls are more liable than boys to suffer from the presence of lice; their hair is allowed to grow long, and seemingly they present a clean appearance, but on turning up the hair in the hollow of the neck there will too often be found a colony of the above-named animals. The children necessarily scratch their heads, a sore is produced, and soon we get matting of the hair and other well-known symptoms.

This is soon cured, but should not occur in any well-regulated school, and it reflects discredit upon those who have the management of the children to have their pupils in hospital from such a cause.

◆

ON THE VINEGARS MET WITH IN DUBLIN.

By H. L. Ferguson,

Associate of the Royal College of Science for Ireland.

A very beautiful and delicate process has been made known by M. G. Witz, (*a*) for the volumetric estimation of acetic acid and the acetates in the presence of free mineral acids; it is based on the difference of behaviour of acetic acid and of the mineral acids (hydrochloric, sulphuric, nitric, etc.) on the *violet of methylaniline*. Acetic acid has no reaction whatever on the violet, whilst the mineral acids, even when they exist in the smallest possible quantity in a liquid, turn it a bluish green.

At the suggestion of Professor Galloway, I repeated the experiments of Witz by employing, in the first instance, measured quantities of pure acetic acid of known

---

(*a*) *The American Chemist*, vol. vi., page 12.

strength, and adding to each portion a measured quantity of sulphuric, hydrochloric, or nitric acid, the strength of which had been previously determined. I found, as Witz has stated, that the quantity of each of the acids, the mineral and the acetic, could be determined with the greatest exactitude.

We require for the determination a standard solution of caustic soda, and estimate by means of it—1st, the total quantity of the acid in the presence of litmus; 2nd, the quantity of the mineral acid in the presence of the *violet*. Having satisfied myself as regards the correctness and applicability of the process, I employed it in examining eleven samples of vinegar obtained at different shops in Dublin. The price of the samples varied from 4d. to 6d. the pint.

The chemical analysis furnished the following results:—

None of the samples contained a trace of free sulphuric or other mineral acid, although the law allows the addition of one part of sulphuric acid to 1,000 of vinegar, and, therefore, it is only when the quantity exceeds that amount that it can be considered as an adulteration. Four of the samples contained traces of sulphates, and all the samples were free from metallic impurities. The following quantities of acetic acid were found to be present in the different samples:

No. 1. Superior pickling vinegar from Boyd and Goodwin's, Marion Row:—
Percentage of acetic acid, 5·10.
Not a trace of sulphates present.

No. 2. Superior brown malt vinegar from Boyd and Goodwin's:—
Percentage of acetic acid, 5·16.
Sulphates, trace.

No. 3. From Kinigan's, Camden Street:—
Acetic acid, 4.08 per cent.
Not a trace of sulphates.

No. 4. From MacLoughlin's, Patrick Street:—
Acetic acid, 4·50 per cent.
Sulphates, trace.

No. 5. From O'Leary's, Stephen Street:—
Acetic acid, 4·92 per cent.
No sulphates present.

No. 6. From Bewley and Draper's, Mary Street:—
Acetic acid, 5·40 per cent.
Sulphates, trace.

No. 7. From Fawcett's, Henry Street:—
Acetic acid, 7·56 per cent.
No sulphates present.

No. 8. From Slattery's, Ship Street:—
Acetic acid, 5·40 per cent.
Sulphates, trace.

No. 9. From O'Brien's, Bride Street:—
Acetic acid, 5·70 per cent.
No sulphates present.

No. 10. From Merritt's, Sir John Rogerson's Quay:—
Acetic acid, 4·92 per cent.
No sulphates present.

No. 11. From Brooks and Wright's, Lower Baggot Street:—
Acetic acid, 7·92 per cent.
No sulphates present.

As vinegar is deemed to be good as regards strength if it contains four per cent. of acetic acid, the eleven samples were all, as shown by their analysis, good in strength, and two of them exceedingly good. The price and quality did not always correspond, one sample which cost sixpence the pint being inferior in strength to some of the samples which only cost fivepence.

Clinical Records.

CANTERBURY HOSPITAL.

Dislocation of Sternal end of Clavicle upwards and backwards.

(Under the care of HORACE MANDERS, M.R.C.S.)

JOHN MARSHALL, 38, van driver, presented himself in the casualty department, stating that the night before he had met with an accident to his shoulder. Whilst putting his van up for the night, not being able to get out of the way, had his shoulder squeezed between the van and the wall. Thinking it was only a sprain, he paid no attention to it that night, and next morning drove sixteen miles before breakfast, when, finding a difficulty in swallowing, and his arm of little use, he came to the Hospital.

On examination, it was found that he was naturally a long-necked man, the top of the manubrium being much more below the level of the point of the acromion than usual. An inch below and slightly behind the tip of the left acromion was a bruise the size of a florin where he said the wheel struck him. On seeing what he could do with his arm it was found that he could abduct it, rotate it either way with ease, and lift it, with some difficulty, nearly horizontally, but on attempting to adduct it and bring the hand to the opposite shoulder, he immediately had a choking sensation that compelled him to desist. It was noticed that the point of the left shoulder was lower than that of the right, and that the convexity of the left clavicle was not apparent; on digital examination, the articular surface of the sternum was plainly felt with the edge of the sterno-mastoid attached, while the fingers could be passed over and along the first rib, distinctly making out the artery, &c. The head of the clavicle was now sought for, and found two inches above the manubrium, somewhat behind and to the left of the trachea, pressing slightly on the œsophagus. No pain was complained of—only a difficulty of swallowing the saliva. The breathing was easy.

Reduction was effected by placing the knee between the shoulders and drawing them forcibly back, while the head of the clavicle was manipulated by two fingers working from behind the slip of sterno-mastoid attached to the sternum, the patient being directed to hold his head so as to relax that muscle. The bone was now in much better position, the head lying just behind the slip of muscle. A figure of 8 bandage was applied over the shoulders and over a large pad between them at the back, and on bringing the elbow to the side, the head of the clavicle was seen and heard to go in with a distinct snap. As it slipped out during the process a weight was attached to the elbow, which kept it in place. The man could not stay in the Hospital, but information was received afterwards, through the courtesy of Mr. Denny and Mr. Fry, that the cure was perfect. The direction of force in this case seems to have been the same as that which occurred at Bungay from curvature of the spine, where the head of the bone had to be removed.

CEPHALIC VERSION ON HAND PRESENTATION.

MRS. FITZPATRIK, a labourer's wife, age about 24, on her second confinement sent for me (1874). On arrival I found a hand presenting, the "waters" had broken some time previously, but the pains were not strong. I at once proceeded to turn and deliver. Whilst introducing my hand for that purpose, the presenting hand and forearm went out of the reach of my fingers in os uteri, and the acromion presented. I found the fœtus very movable in utero, notwithstanding the fact that the liquor amnii had escaped, so it struck me that by a little manipulation I might succeed in making a head presentation of it without the necessity of introducing my hand completely into the uterus. Accordingly, with the fingers of one hand in os uteri (which was sufficiently dilated for delivery), and with the other hand on the abdomen, I managed to bring the head into apposition with the brim of the pelvis, and left it there. Uterine action went on naturally, but feebly for some time, until the head was well down in the pelvis, when inertia set in, on which ergot had little or no influence, and I had to complete delivery with the forceps. The child, a very small one, was delivered alive and strong. I had no difficulty in applying the forceps, but had to remove the placenta, which I found slightly adherent.

My next similar case occurred in about a year afterwards. The paid midwife of my district, in attendance on Mrs. Burke, a stonemason's wife, sent for me. I found, as in the other case on my arrival, that the "waters were gone," and a hand presented. I lost no time in my attempt to deliver by version, but found that the slightest attempt to introduce my hand brought on violent uterine action, and it was with considerable difficulty, and after a good deal of patient waiting with my fingers in os uteri, that I succeeded in passing my hand in an interval of rest into the womb. I passed it on the anterior surface of the child, but although I felt the foot I could not grasp it, because my hand was completely cramped, owing to the severity of the uterine action, and I had to withdraw it, but in doing so, it *accidentally* brought the head into position for natural delivery. Uterine action, unaided in any way, completed the delivery of a living healthy child in about one hour afterwards.

In the first case, my object was to avoid, if possible, the necessity of a complete introduction of my hand into the womb, and the great mobility of the child tempted me to try the experiment. I think the attendant circumstances and sequelæ justified it. Yet, had I foreseen the inertia and retention of placenta which necessitated the introduction of my hand afterwards, I think I would have adopted podalic version. The second case was purely the result of *accident*. Yet, in conjunction with the first, it goes far to convince one that the operation may be performed in many instances, and with more safety to the mother and child than podalic version.

Since the occurrence of the above, a case of elbow presentation, which terminated by *spontaneous expulsion*, occurred in my practice. I was not sent for till the membranes had ruptured, when the midwife, for the first time, discovered an abnormal presentation. On arrival I found the elbow at os externum. Owing to the intensity of uterine action, I could not introduce my hand. After several attempts I desisted, and sent for another medical man to hold a consultation; before his arrival the case had terminated by spontaneous expulsion, almost exactly as Dr. Douglas has described it. "The uterine action was the most intense I have ever witnessed, in fact, it was *terrific*, and I feel asured that if it had been in a less robust, healthy, well-developed muscular woman, the uterus could not have withstood the strain. She is the wife of a farmer (Mrs. Hickey), and it was her third confinement. I allude to this case merely on account of its rarity. The child was stillborn, but the mother had not one bad symptom during convalesence.

P.S.—I had to send six Irish miles for a consultation.

◆

We observe that a very high rate of mortality exists in many of the chief cities of the world, notably in America. New York is highest on the list, with 64 per 1,000 of its population—a terrible rate. Brooklyn 55, Philadelphia 54, come next. India contrasts very favourably with these figures; thus, Madras 38, Bombay, 28, Calcutta 23. A high rate also prevails in a few of the cities of Europe; Buda-Pesth having 48 per 1,000, Berlin 46, Munich 36. Fortunately descending still lower in our own cities, London with its four and a half millions yielding only a death-rate of 25 per 1,000, Dublin 21, and Edinburgh 20.

CHOLERA EPIDEMIC OF 1873 IN THE UNITED STATES. (*a*)

America is making wide and rapid strides in the cause of state medicine. The number of valuable reports on public health published in the United States bid fair to surpass those of the old country. The work before us is a report of a most elaborate and painstaking investigation into the mode of introduction and progress of cholera in America during the great epidemic of 1873. Our space will not permit us to give in detail any of the special points noticed by the author, but it is sufficient to state that every question connected with the history and progress of cholera is carefully recorded. The disease is carefully traced from its home in India to its invasion of America. Each local outbreak in America is carefully treated of, and every promoting cause considered. The work concludes with a voluminous bibliography of cholera, by Dr. Billings, Assistant-Surgeon United States Army. This portion of the work occupies upwards of 300 pages, and comprises reference to nearly every known writer on the subject. Dr. Billings states that 8,000 volumes of medical journals were consulted in the celebrated medical library of the surgeon-general's office at Washington.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 16, 1876.

THE DEATH OF MR. BRAVO.

The remarkable and protracted inquiry into the death of Mr. Bravo has at last drawn to a close, and we feel it our duty to make such remarks as naturally suggest themselves to a profession which has been in no small measure mixed up with the lamentable events at Balham. Nor can we merely regard this case from a strictly scientific or professional point of view. Used as we are to witness many painful scenes, we cannot look with indifference upon the fate of that young man, who, amid the pleasures and luxuries of life, has been suddenly summoned to an untimely grave.

There is not, perhaps, in the whole annals of medical jurisprudence, a case in which the question of suicide was enveloped in so much mystery as that which has been riveting the attention of the public for the last two or three weeks. As Casper truly remarks, "in the case of poisoning there is seldom any doubt whether death has arisen from suicide or from the crime of a third party." And he rests this assertion only upon the nature of the poisons which are usually selected for suicidal and homicidal purposes respectively.

But with regard to the death of Mr. Bravo, what a variety of facts, and what conflicting evidence, have been adduced to mystify the case, and that too under circumstances which rendered the mystery still more mysterious. Here is a man, who, although dying by violent means, is ill for three days before he dies. During nearly all that time he is perfectly conscious and in the full possession of all his faculties. He is from the commencement assiduously nursed by his nearest relatives. He is repeatedly examined and cross-examined by the medical men in attendance as to what he had taken. A long and searching inquiry is made in which every witness who can throw any light whatever upon the matter is brought forward, and in which eminent counsel appear in behalf of the chief actors in this pitiable drama. And yet, although the coroner's jury has found a verdict of wilful murder against some person or persons, there will evidently be grave doubts in the minds of some as to whether he did not after all commit suicide. That such may be the case, and that there are some whom the verdict will take by surprise, is apparent from the ludicrous blunder of an evening paper, which, wishing to anticipate the verdict of the jury, and believing that the verdict would be an open one, went so far as to say that the jury had actually found that there was no evidence to show how the poison was administered or taken. In fact, "down to the last moment," as remarked in one of our leading daily papers, "public opinion was strangely divided, and in every quarter conflicting conjectures were hazarded," and certainly there was wanting many links in the chain of evidence by which the question of suicide is usually so easily disposed of. There was not the conventional discovery of a dead man with an empty bottle labelled "poison" found by his side. There was no written letter found after his death to account for his rash act. There was no such great despondency of mind observed prior to his death, and no such strong motive, as would be almost alone sufficient to account for his suicide. On the contrary, he himself repeatedly declares that he had taken nothing but laudanum, which was well known not to be the cause of his death. The poison, about the nature of which there was no question, is the very last that would be chosen by anyone with suicidal intentions, and especially by one who had evidently some knowledge of medicine. Nor could it be shown how he had gained possession of the poison, while, finally, there was not wanting some strong circumstantial evidence to throw suspicion upon other parties.

To review here this remarkable case in a satisfactory manner, especially in its toxicological or medico-legal earing, we must go back to the beginning. We cannot wonder that at the outset there was some doubt as to the nature and cause of Mr. Bravo's illness. The profound and prolonged state of collapse in which that gentleman was found, and the suspension of the heart's action, might have been owing to natural causes. On the other hand, the symptoms somewhat resembled those arising from narcotic poisoning, without corresponding to those usually observed in either poisoning by opium or by chloroform, and even when the symptoms were more fully devoloped, it is quite possible that had Mr. Bravo been a poor man and attended by an ignorant practitioner the real nature of his case might never have been discovered, especially as he himself did not entertain any supicion of having been poisoned, and denied having taken any himself. But the professional ability which was brought to bear upon the case soon made out that the unfortunate man was neither suffering from gastritis., enteritis, dysentery, nor any other disease, but from an irritant poison, the exact nature of which, however, could not for obvious reasons be so quickly determined. Sir William Gull and Dr. Moore thought it was arsenic. Dr. Johnson suggested corrosive sublimate. A chemical analysis alone showed it to be antimony. Moreover, both the symptoms and the *post-mortem* appearances were in this case very remarkable, if they did not show that something else besides antimony had been taken. We all know that in some cases of poisoning by tartar emetic, temporary syncope, loss of consciousness, &c., will be produced, but these symptoms are comparatively evanescent, and have only been observed when very large doses have been taken. Taylor, in the last edition of his work "On Poisons," mentions several such cases. But if Mr. Bravo had taken such a large dose of antimony as to give rise to the severe and prolonged collapse under which he first laboured, it seems strange that after death there was scarcely any trace of that local irritant action which almost invariably arises from the swallowing of a large quantity of this poison. At all events, this prolonged collapse and comatose condition was very remarkable, and will be certainly worthy of record in our future text-books of toxicology. With regard to the *post-mortem* appearances, it is, indeed, very remarkable that the throat, gullet, stomach, and small intestines should have been free from those changes which have been generally observed after death from irritant poisoning; and this circumstance can only be accounted for on the supposition that the poison had been taken largely diluted, and that a large portion of it had been rejected by the stomach.

We now come to the most important question of all—that of suicide or homicide. A good deal of the obscurity in which this question has been enveloped was owing to the fact that up to the time of his death, Mr. Bravo persistently denied having taken anything but laudanum, as well as to the fact that it could not be shown how he got possession of that poison. It is not however for us to dwell upon these points, as we have to confine ourselves more to the medico-legal aspects of the case.

Against the theory of suicide much superfluous evidence was adduced to show that he was not a likely man to commit such an act, and that he always appeared in good spirits. But such evidence was almost worthless, and a mere waste of time. Who can tell that a man is not likely to commit suicide? Every chemist knows that while the converse prognostication may be often very confidently entertained, it is impossible to predicate from a man's apparent state of mind his exemption from propensity to suicide. As Mr. Smith very pertinently remarked, one of his own and oldest friends who committed suicide was one of the "jolliest" fellows he ever met with. The fact is, we can only draw inferences as to a disposition or not to suicide from that state of mind and general demeanour which immediately or very shortly preceded the rash act. No one, for instance, ever committed suicide when he was in good spirits. No one could be accused of poisoning himself who had sat down to dinner in the best of health, and in the best of humours, and was shortly afterwards attacked with symptoms of acute poisoning. And as it has been clearly shown that such was, with one or two reservations, the condition of Mr. Bravo's health, and such the state of his mind for several hours previous to his illness, we must allow that the theory of suicide had little or no foundation to rest upon.

Another grave objection to the idea of Mr. Bravo having poisoned himself is the uncertain nature of the poison itself, and the very painful nature of the symptoms attending its action. Tartar emetic has been used for homicidal purposes. It has been frequently taken in large doses by mistake. It has perhaps never been used for the purpose of self-destruction. And considering the position and abilities of this unfortunate gentleman, and that he had evidently some slight knowledge of medicine, it seems the more improbable that he would have taken such a drug with the intention of committing suicide. But the gravest objection of all to the theory of suicide was, undoubtedly, his own repeated denial of having taken anything except laudanum. On this point the medical evidence was particularly valuable, although it must be confessed that this evidence was rather vague and conflicting, and if we carefully peruse this evidence, which, had we space, we should like to quote, we must admit that the confession of the dying man, both to Dr. Johnson and to Sir William Gull, was not so decided and altogether not so satisfactory as was desirable. It did not occur to any of the medical witnesses to ask him pointedly if he had taken any poison for the purpose of self-destruction. Had they done so his answers would not have been of so evasive a character as they appear to have been. As it was, he never said in unmistakable terms, that he had made no attempt upon his own life, and he did not show any suspicion or fear of either having taken any poison by mistake or having been poisoned. Indeed, his general demeanour after he had been told he was dying from the effects of poison, and the absence of all that trepidation and alarm which we would naturally look for in a man who suddenly finds himself either accidentally or criminally poisoned, was certainly one of the most striking features of this extraordinary case.

If, however, we review the whole evidence, and take into consideration what we, as medical men, know of suicide in a medico-legal point of view, we cannot find fault with the verdict of the jury, and can only regret that, with the exception of this question of suicide, the verdict leaves the Balham mystery almost as much a mystery as it was prior to the inquiry.

THE SHEFFIELD MEETING.

The British Medical Association received undoubtedly at its last meeting, from its hosts of the iron metropolis, that which the Brighton doctors, with or without good reason denied to it—a right hearty English welcome—and if the meeting had proved an unsuccess, the responsibility must have been placed elsewhere than upon the hospitable intentions of the medical men of Sheffield. In truth, it can be no subject for wonder that the practitioners of any but the largest towns should hesitate before, by a formal invitation, they pledge themselves to the entertainment and amusement of four or five hundred doctors voracious for the holiday excitement of their once-a-year trip; and of late years the hospitalities of the Association have become so onerous, that it occasions no surprise to learn that invitations are becoming scarce, and that the Council finds itself without a place of meeting for 1877.

The gathering which has just broken up was by no means one of the largest, and perhaps for those who were present that fact was no subject for regret, but it was in all respects a decided and deserved success, and while it has in no respect detracted from the *prestige* of the Association, it has done credit to our medical brethren of Sheffield, both to their heads and to their hearts. The address in surgery of Mr. Favell was a thoroughly practical exposition of the application of science to his art, and a valuable contribution of the result of long experience in a centre of industry, where surgical experiences are abundant and instructive, and the observations of Mr. Brown-Séquard were of great worth as a theoretic indication of the direction in which surgeons may best apply the opportunities of observation which a great manufacturing town affords them. Of the sectional works of the Association, those of the Public Health Division and of the Obstetric Section were certainly the most valuable. In the former especially the communications upon the inebriate question and upon the contagious diseases controversy, and the debates upon these subjects, displayed both ardour, talent, and experience in the investigations of these difficult subjects, and inasmuch as these questions of public health can only be effectively discussed in a conclave of experts, and by an interchange of the ideas of many thinkers, the best result may be anticipated from the proceedings of this section.

The social attractions of the past meeting of the Association proved to be greater than the visitors had any hope for, for the epidemic of hospitality seemed to have spread from the medical entertainers of the Association to their non-medical friends, who vied in doing honour to the stranger doctors. There may be many meetings of the Association yet to come, but there will be few more successful under all the circumstances than that just closed.

◆

VIVISECTION BILL.

This Bill has now been read a second time, and to our great regret, we add, with a withdrawal of opposition on the part of some of its opponents. We cannot understand indeed the change of tone in some of our contemporaries. The *Lancet*, which has shown a perfect indifference to the whole subject, is naturally not dissatisfied with the Bill as it now stands. The *British Medical Journal* seems to acquiesce under pressure, on the vulgar principle that half a loaf is better than no bread. But surely this important matter is not to be decided in such a loose manner. The Government have made a mistake, and they recognise it, and no one would be more anxious to drop the Bill and to conciliate than the Home Secretary himself; but he fears to acknowledge that he has displayed a weakness throughout the whole transaction. In a long and conciliatory introduction to the second reading of the Bill, he in plain words states that the Bill is a preventive and not a curative, that legislation is not so much required for the present as for the future. But what is to be thought of a minister whose object is to legislate for the unknown, who devotes his time to the making of laws to prevent what will probably never occur, whilst he neglects to give consideration to matters of national importance requiring immediate interference? And to look at it in another light, what would the people say of a minister who, recognising the necessity of some great national law, should after prolonged discussion and expenditure of invaluable time in the constitution of that law, apply it only to Rutland, the smallest nook in the empire? Yet to such in truth the Vivisection Bill bears great resemblance. The suffering to be relieved by the Vivisection Bill resembles the smallest nook; it is but the smallest iota among the forms of cruelty to animals. The columns of our daily papers teem with reports of heartrending cruelty to *man* and other animals. A man—let us call him a *brute*—may bruise, tear, and lacerate—worse than vivisect—his wife almost with impunity; but he who makes the smallest cut on a member of the brute creation for the benefit of the human race shall be branded a vivisector. Is this right? Is it fair? The Bill is *cruel* in itself to a class, whilst it touches but the minimum of infliction of pain upon animals; and that minimum of pain, which it is intended to prevent, is the most justifiable—if not the only justifiable—torture of the lower animals. It is said that this Bill affects the honour of the medical profession, charging them, who least deserve it, of all classes of mankind, with cruelty to animals. Such is undoubtedly the case; but it is not on this point alone that we object to the Bill. We can afford to laugh at our mockers; and though taunted with cruelty, we will pity them in their ignorance, and lay not the sin to their charge. We cannot express surprise at the Bill as it now stands. On the contrary, we may expect other Bills to spring up, calculated even more than the one under consideration to stand in the way of, and to prevent the advance of, science. When an influential law lord can face the House of Lords, and suggest the possibility of meeting the lower animals in a future world, we can scarcely be surprised if his next Bill should have for its object the prohibition of the cure of disease as a defiance of the actions of the Almighty, and we warrant that such a Bill will meet with not a little support.

But with regard to the objections to the Cruelty to Animals Bill as it now stands. We are bound to say that it materially differs from the outrageous and retrograde Bill originally introduced, but several of the modified clauses, we unhesitatingly assert, will still essentially retard the advancement of medical science.

We refer to the several special licences and to the registration. For instance, a physician or surgeon recognises a diseased condition or chain of symptoms which he cannot explain; he will probably endeavour to elucidate the matter by experimentation upon guinea pigs, for which he will obtain a licence, and thus become a known vivisector: if anxious to follow out his experiments upon a larger animal or upon a flesh-eating animal, he will be compelled to obtain another special licence. Is a physician, already overworked, likely to undertake so much extra trouble, and of so annoying a character? No; he will either evade the law, or, with a passing regret, throw aside the investigation. Such instances will constantly occur.

Again, turn to the power of the Home Secretary in dealing with these licences. So long as Mr. Cross holds office it is a matter of little import, for we believe that he would really use his influence to increase justifiable vivisection; but what if Mr. Holt should one day hold that position? We do not at all anticipate that that luminary will, and we sincerely trust he never may be raised to the position of a Secretary of State; but if by chance he or one of a similar mind should be, then experimentation upon lower animals may be said to be at an end.

No, whatever becomes law must be decisive, and must not be left to the caprice of an ever-changing minister. Again, we urge that the Bill, as it now stands, is not fitted to become law.

We contend that the names of those who seek a licence should not be registered or made public, and that the special licence clauses should be removed. They are not needed, and if retained they will, for the reasons given, retard the progress of science.

It is to be hoped that those who have hitherto fought so successfully against the Bill will yet demand either a withdrawal of these clauses in Committee, or else a withdrawal of the whole Bill.

If the Government desire to gain prestige, they may with grace shelve the Bill for the present session, and next year embody a sufficiency of it in a Cruelty Bill on a larger scale, and they will have the support, instead of, as now, the opposition of the whole body of the medical profession unexceptionally.

◆

RECENT CHOLERA REPORTS.

IV.—The Prevention of Cholera.

As regards the transportation of cholera from one country to another, there is no means of *prevention* which has been so much relied upon, or upon which so much has been written, as that of quarantine. The strict enforcement of quarantine, however, is not so much in favour at the present day as it formerly was. "If, then," remarks Mr. Simon, "human contagion is the one active power in the international spread of cholera, is it possible so to restrict the intercourse between infected and non-infected countries as to prevent the spread of the contagion?" In answer to this question, Mr. Simon submits, as he did also in his 8th Annual Report to the Lords of the Privy Council, that quarantine, "of a sort to be trusted in as a national defence, is not conceivable except in proportion as a people lives apart from the great highways of commerce, or is ready and able to treat its commerce as a subordinate political interest." In corroboration of this opinion he points to the many facts in Mr. Radcliffe's Report, which show how utterly futile were the quarantine establishments of Europe in 1865; and in another place Mr. Simon remarks: "If the constant development and constantly accelerated communication between India and the rest of the world is not to carry with it a constantly increasing terror of pestilence, the safeguard, I apprehend, will consist not in contrivances of the nature of quarantine to maintain from time to time more or less seclusion of nation from nation, but rather in such progressive sanitary improvements on both sides as will reduce to a minimum, on the one side the conditions which originate the infection, and on the other side, the conditions which extend it." Again, Mr. Simon observes that the practice of this country has long recognised that little or no control can be exercised at ports of arrival except as to persons who are found manifestly infected with the disease. "Control to this limited extent, not pretending to efficiency as a measure of national defence, but able to be of some local value . . . . is what this kingdom has in place of quarantine; and it is satisfactory to read . . . . how strongly the balance of European opinion is now inclining to the side of our English practice." There are few who will fail to see the sound practical advice conveyed in these observations; but it may be doubted whether even the old system of quarantine should be altogether abandoned. There is plenty of evidence to show with what success quarantine may in some instances be enforced, and to show that it should still be practised wherever it can be carried out with vigilance and with little interference with the mercantile interests of the place. "It has been clearly demonstrated," says one of the American reporters, "that the City of New York was in 1873 secured from four distinct importations of epidemic cholera by the rigorous quarantine of observation," in which, among other precautions, each case was isolated, and disinfectants judiciously employed. We may also add that while the International Sanitary Conference came to the conclusion that quarantine by land was impracticable and useless, it expressed its approval of quarantine by sea, and concluded that, with the view of preventing fresh invasions of Europe by cholera, the measures recommended by the Conference of Constantinople should be adopted, and that, moreover, quarantine, especially in the Red and the Caspian Seas, should be carried out in as complete and satisfactory a manner as possible.

We admit, however, that quarantine cannot be entirely relied upon as a means of preventing the importation of cholera from one country into another, and therefore it is all the more incumbent upon us to do all we can to restrict the spread of the disease wherever it has gained a footing. Now, of all the conditions upon which the spread of cholera depends, filth, in all its forms and manifestations, is the most potent; not only has our own medical officer of the Privy Council insisted over and over again upon the deplorable consequences arising from the filthy condition of places where cholera has made its appearance, but, as we have already mentioned, every page of the American Reports bears testimony to the truth of the many strong statements which Mr. Simon has made with respect to "Filth Diseases and their Prevention." The space at our disposal, however, will not allow us to enter fully upon this topic; suffice it to say that the term "filth" is to be taken in its widest acceptation, as bearing reference to filthy conditions of water-supply, to bad drainage, to bad ventilation, and impurity of the air, to the presence of infected articles of clothing, and to all kinds of dirty habits. From these Reports we see that, among the very numerous outbreaks of cholera which, in 1873, occurred in various parts of the United States, there is scarcely one which does not show that the epidemic was either occasioned or much aggravated by the existence of one or more of the above conditions, while in many instances it was equally well demonstrated that where due hygienic precautions were taken the spread of the disease was either at once arrested or confined within very narrow limits. It follows therefore that too much stress cannot be put upon the necessity of securing good drainage, good and pure water supply, goo ventilation, and perfect cleanliness, in any district in which cholera has appeared; and that, moreover, if nothing else is done but the removal of all sources of filth we shall have very little to fear from future invasions of cholera.

With regard to the question of *disinfection*, to which we must now devote a few remarks, the Vienna Conference came to the conclusion that there are no means of disinfection known by which the generative or contagious principle of cholera can be certainly destroyed or deprived of its intensity; but the members of the Conference were unanimous in recognising "the great value of hygienic measures, such as ventilation, thorough cleansing, &c., combined with the use of the substances regarded as disinfectants." Pettenkofer's opinions on the subject are to the same effect. He thinks we ought not to abandon disinfection, for it may have hitherto proved unavailing because the cholera-poison does not exist exclusively or even at all in the excrements, or because we have not employed the proper disinfectants, nor employed them in the proper quantity nor in the proper manner. He very justly observes that the value of disinfection "as an essential means of maintaining cleanliness cannot be denied," and that, on the principle of our health and resistance to disease being very much influenced by the purity of the air we breathe, the disinfection of excrements, privies, &c., has advantages independently of the questions whether they contain any specific poison or not. The profession in America, on the other hand, are very unanimous in the favourable opinion they hold as to the great and specific efficacy of disinfection, an opinion which appears to be strengthened, and perhaps biased, by their equally unanimous opinion that the active agents in the distribution of cholera are the dejections of persons suffering from the disease. The able writer of the introduction to the American Reports remarks:—"What vaccination is to small-pox, hygienic regulations are to cholera. The rigid observance of sanitary laws presents to this virulent disease a wall which is almost insurmountable. The foundation of this wall . . . is undoubtedly laid in disinfection." And if we turn to the Reports themselves, we certainly find that the truth of this proposition is strongly corroborated, although not absolutely proved, by the testimony and opinions of various witnesses. Thus, in one place, we read that "the dejections from these two patients were disinfected and buried, the bedding and clothing were burned; the bodies were disinfected. No other cases occurred." In another, we read that on the first symptom of the outbreak in Cairo, Illinois, "the city authorities caused the city to be thoroughly policed. All low, damp places, all privies, &c., were disinfected with sulphate of iron, carbolic acid, and lime. The cases that occurred were isolated, and their excreta thoroughly disinfected. It is undoubtedly the fact that by this thorough system of disinfection the city of Cairo escaped a most serious epidemic; for, &c. . ." Again, at Okawville, Washington County, "the intensity of the disease was owing to its low, malarial situation, and the violation of all hygienic precautions to arrest or control the epidemic," whereas at Addisville, in the same county, "the most rigorous measures were adopted for its arrest by disinfectants and the destruction of bedding and articles of clothing, it was stamped out in two days." We might go on multiplying instances of this kind, but the above extracts are sufficient to show the importance which the American physicians attach to the thoroughly systematic practice of disinfection.

With regard to the kind of disinfectants on which most reliance can be placed, both American and European authorities speak very highly of *sulphate of iron* and *carbolic acid*. But, as Pettenkofer observes, it is not enough merely to use some sulphate of iron and some carbolic acid; they must be used in sufficient quantity. And this quantity is that which will render the excrements acid, and will keep them so until they have been removed from the house, as the cholera-excreta vitiate the air most when they are allowed to become decomposed and to undergo alkaline or ammoniacal fermentation. Linen and cotton fabrics, says Pettenkofer, may be most simply disinfected by being steeped in hot lye made with freshly-slacked lime, so called caustic lye. Woollen articles, cloth, feathers, &c., may be boiled in water or fumigated with sulphur. This eminent authority says little or nothing respecting the disinfecting properties of fresh earth, although the value of this agent as a disinfectant is generally acknowledged, and was fully demonstrated during the late American war. The means adopted by the American reporters, and to which as we have seen so much efficacy is attached, were certainly very thorough and systematic. Thus, among other measures adopted, a deep but narrow pit was dug in the yard adjoining the patient's house, and the bottom of it covered with the sulphate of iron. Each vomit or dejection was then mixed with a saturated solution of the crystals, and emptied into the pit, a few inches of earth being thrown upon each dejection. Where the cholera-excreta had to pass into drain-pipes connected with sewers, each vessel containing the excreta was thoroughly disinfected, and the drains frequently flushed with a concentrated solution of the sulphate. All soiled or infected articles of clothing or of furniture were, if possible, either put into a large wash-tub filled with a strong solution of sulphate of zinc, or of chlorinated soda, or burned at once. If the case terminated fatally, all the clothes and soiled linen were at once removed and thrown into the tub containing the disinfecting fluid. All waters that had been used for washing were disposed of in the same manner as the excreta. Mattresses, if soiled, were destroyed; and the body, after having been thoroughly washed and disinfected, was placed in the "casket" surrounded with crystals of sulphate of iron or of permanganate of potash.

At the outset of our remarks on these reports we intimated that we could not take a comprehensive view of the transmissibility and prevention of cholera, apart from the diseases of endemic prevalence in India, and on this point the remarks of Mr. Simon are so concise and practical that we cannot do better than conclude this paper by drawing the attention of the reader to them.

With regard to the conditions of the spread of cholera over large areas of the Indian continent, Mr. Simon observes that we must take into consideration "the same property of contagiousness, and the same relation of this property to circumstances of filth, as we know to be the essential conditions for the extension of the disease in Europe;" that "the amount of cholera-diffusion in India is likely to be controlled by the same preventive measures as are certainly effectual for the like purpose in Europe," and that the transportation of the disease from India will be less and less, "in proportion as common sanitary government shall more and more bring within control the common filth-diseases of that vast country. And from this point of view it is most hopeful to know that for many past years . . . the British Government has been organising in India such provisions for sanitary government as promise soon to compare not unfavourably with the present institutions of Europe itself." "The distinctive Indian problen, however, is that of the endemicity of cholera in part of the Indian area." It is from within British territory that cholera sallies forth from time to time, and in lower Bengal this disease is said to be as normal to the district as ague to the marsh-lands of Europe, and as definitely related to the seasons as if it were a fruit of the earth." To learn the conditions of that endemicity is a problem of the highest science, and to control them in the interest of mankind will be among the noblest administrative tasks which the responsibilities of empire have ever imposed . . . but her Majesty's Government, now for some years past, has been promoting the study of cholera in India with the best lights of contemporary European knowledge; and no one will doubt that here, as in other departments of medical research, truly scientific study must eventuate in practical good."

We have devoted some time and labour to an examination of these voluminous reports, not only on account of the great importance of the subject, but because those issued from the American press do not appear to have attracted in this country the attention which they deserve. It is to be hoped that some of the recent facts and opinions respecting the transmissibility and prevention of cholera to which we have endeavoured to draw attention, will not only be found to be of some interest, but will show our professional readers, and through them the public, the good results that, in any future invasion of this country by cholera, may be expected to follow from rigorously adopting those means of prevention and those sanitary precautions which have been dictated by science and by our experience of former epidemics.

◆

Notes on Current Topics.

The Sick and Wounded in the War in the East.

If we are to judge from accounts that have recently appeared in the daily papers, whatever political sympathy we may have shown for the Turkish cause, we cannot say that much is being done for their sick and wounded. In this respect all the sympathy appears to be on the side of the Servians. Mr. J. Lewis Farley, Secretary of the League in Aid of the Christians of Turkey, states that their medical representative, two ladies, Miss Pearson and Miss M'Laughlin, are on their way to Belgrade with a large supply of hospital stores, medicines, lint, bandages, &c., and that more surgeons, hospital dressers, trained nurses, and hospital stores will soon follow. Of course the Russians are not behindhand in sending to their *protégés* medicines and medical aid, as well as arms and soldiers. And well they may, considering the large share they have had in fomenting this lamentable insurrection, and the enormous amount of carnage, misery, and suffering that can be laid to their charge.

> "The Russian Society of the Red Cross, which is under the patronage of the Empress of Russia, has appealed through the Russian Embassy at Vienna to the Foreign Office for permission to pass through Austrian territory the sanitary train and personal staff destined for Servia. A similar train, consisting of 300 large cases and packages, in charge of two medical men, and with a number of dressers and nurses, was sent some time ago to Montenegro. The sanitary train will not arrive before it is wanted, for, according to all accounts, the sanitary service in the Servian army is deplorable. Dr. Mudny, an Austrian medical man, at present at the head of the sanitary service of the Servian armies, has just addressed by telegraph an appeal to his colleagues, the Austrian army surgeons, asking them in the name of suffering humanity to get shorter or longer leave and come to his aid as speedily as possible. He promises them the most friendly reception and a rare opportunity for acquiring practical knowledge in this war, which for cruelties of every kind, he says, stands unique in the history of wars."

We are, however, glad to see from a long advertisement in the daily press that the "Eastern War Sick and Wounded Relief Fund" is to provide medical and surgical assistance for the sufferers in the war irrespective of nationality, that it will act under the rules and regulations of the Geneva Convention, and consequently without any political aim or object. Dr. Laseron, Mr. A. O. MacKellar, assistant-surgeon, St. Thomas's Hospital, and six other surgeons, have proceeded to the seat of war, and will with others about to follow send reports to the committee of the above fund. A telegram has already been received from Dr. Laseron, who says that at the hospital at Porgarenatz (?) there are 400 wounded and only one doctor. He also hears that some thousands have been wounded in the last few days, and strongly appeals to the English public for further help.

Taunus Natural Mineral Water.

This, which may be classed among the most delicious of our table waters, is obtained from a spring in the Grand Duchy of Hesse, near to the Taunus range of mountains. It contains in small quantities the chlorides of sodium and potassium, carbonates of lime, soda, and magnesia, with faint traces of other salts, sulphate and phosphate of lime, silica, and alumina. It is said to contain about 17 in 10,000 parts of carbonic acid in solution, and 29 parts compressed, upon which latter depends its sparkling character. The above analysis shows it to have no medicinal property. It is an agreeable effervescing drink, without colour or smell, and leaves a pleasant, soft, and clean flavour upon the palate. If a bottle be partly emptied and recorked, and placed in a cool place, the water will retain its briskness for some days.

The Rivers' Pollution Bill and our Water Supply.

The Pollution of Rivers' Bill has become law, but this will in nowise help to lessen the evils attendant upon the long drought. From all parts of the country there comes a cry for water; in many country places there is quite a famine, and the inhabitants are, we are told, restricted to the use of water for drinking purposes. This is indeed a terrible state of things, and if a remedy is not soon forthcoming must end in some sad calamity. Of what avail is it to prevent further pollution of rivers if steps are not immediately taken to find a wholesome supply of water for their immediate needs? If people are driven to drink water two-thirds of which is little better than sewage, or the refuse of a deleterious trade, a frightful outbreak of typhoid fever or other disease must ensue. It is strange that there has not been a greater outcry; but then it is only the lives of human beings at stake. Had it been that of dogs and cats there would, in all probability, have been a deputation to the Home Secretary to urge some action, as the digging of wells and grants of money. Whilst your sentimental people are eager enough with their money and time to get up a sensational outcry against the profession, there are apparently, few ready to follow in the footsteps of a member who, in a letter to *The Times* a week ago, told how "in a village only a few miles from London (Surrey) the people had no other source of water than the filthy and poisoned ditches near their cottages. They drank the water of a stream, the privies on the side of which were within sight of their own windows." He was moved to remedy the terrible evil, and believing that water might be got by sinking a well, if he went deep enough, set to work at his own expense, and at three hundred feet struck a vein of pure water—"delicious, pure, cool, and fresh tasting." This he conveyed into a drinking fountain near his house, and now "from earliest dawn to dewy eve" the village waggoner and the thirsty tramp find a means of allaying thirst and avoiding the public-house, formerly their only resort, and close by the fountain.

Militia Surgeons.

In the House of Commons on Friday last, in reply to Capt. Nolan, Mr. Hardy said that the income of militia surgeons derived from the army votes depended upon so many considerations that it was impossible to say whether under a new warrant it would be reduced in some cases by over £100 a year. It depended upon the establishment of the regiment, the number of recruits, whether the regiment went out for training, and whether it went out for a long or a short period.

Prosecutions for Non-Vaccination.

In the House of Commons on Saturday last, in reply to Mr. James, Mr. Sclater-Booth stated that he was aware that Mr. Abel had been fined five times at the instance of the Farringdon Board of Guardians for refusing to have his child vaccinated. He communicated with the guardians some weeks ago, stating that in the opinion of the Local Government Board proceedings of this kind should not be frequently repeated without special care being taken to ascertain whether the repetition of the proceedings was likely to secure compliance with the law. The guardians had replied to this communication fully, and had stated that the fines were paid by an anti-vaccination society. He had done what he could to induce the guardians to consider carefully what they were doing. He could not say that on general grounds he agreed with the policy of the guardians, but at the same time the law had vested them with a certain discretion, and it was not competent for him to interfere with that discretion.

We think this statement by the head of the Local Government Board most unwise and likely to lead to dangerous consequences. It says in effect that a person may be prosecuted for non-compliance only so far as shall determine whether such prosecutions have the effect of compelling him to give in; when it is seen that he intends to continue to set the law at defiance the said person is to be let alone. Whether intentional or not on the part of the Government, we consider that the anti-vaccinators have scored a decided victory.

Alleged Death from Vaccination.

Last Tuesday Mr. Sclater-Booth stated in the House that he had received a statement from Mr. and Mrs. Fag, of Andover, to the effect that their infant child died from the direct effects of vaccination; but an inspector who had investigated the case had been informed by the medical man that death resulted from bronchitis. As, however, Mr. Taylor gave notice that on Friday he would call attention to the case, we shall reserve our comments till we hear what Mr. Taylor has to say on the subject.

Action for Malpractice.

A short time ago a case of this kind was tried at the Worcester Assizes, in which the defendant, Mr. John Alexander Cooksey, gained the day, and the words of the jury, "left the court without a stain upon his character." We now hear of another action brought against a medical man for negligent treatment. The plaintiff, a Mr. Church, alleged that he had gone to the defendant, Mr. Slod, for the cure of a bad leg, and after long attendance and no improvement, consulted Mr. Hutton, the eminent bone-setter, who declared that his thigh was out of joint, and put it in. He accordingly considered that the defendant had been unskilful in not detecting this condition, and sued him for damage.

Mr. Serjeant Sleigh for plaintiff; Mr. Scott, Mr. Day, Q.C., and Mr. Woodhill for the defendant.

At an early period of the plaintiff's case Serjeant Sleigh announced that he had suddenly received an intimation that Mr. Hutton, a witness most important, indeed, indispensable to the proper proof of his case, could not attend before Tuesday; consequently, he felt unable to conduct his client's case with a probable chance of success, and appealed to his Lordship to adjourn the case.

Lord Coleridge observed that this could only be done upon the usual terms—viz., the adjourning party bearing all the costs of the day.

Eventually, Mr. Day waived any objections, as he desired a full inquiry, but as he could not consent to any further hanging over his client of this imputation, a nonsuit was entered by the plaintiff without prejudice to his right to commence any proceedings hereafter.

Plaintiff nonsuited accordingly.

It is to be hoped that we shall hear no more of this case, as in all probability the imputations that have been cast upon Mr. Slod rest upon little or no foundation, as it is not likely that a qualified surgeon would fail in recognising a dislocated thigh. It might, however, be one of those cases to which Sir James Paget some time ago drew the attention of the profession, and in which the rough treatment of the "bone-setter" was reputed to be in some cases beneficial.

Measles in the Fijian Islands.

From a discussion which took place a few nights ago in the House of Commons between Mr. Hunt and Mr. Shaw-Lefevre, it does not appear that the medical officer of the *Dido* was so much to blame as was first supposed.

Mr. Hunt said his noble friend the Secretary of State for the Colonies had stated, in the letter referred to, that he was unable to arrive at any decided conclusion as to the proportion in which the blame for the grave neglect incurred in this lamentable affair should be divided as between the naval and the colonial officers, though he could not admit that the captain and medical officer of the *Dido* had cleared themselves of the charge of having failed to give the fullest notice by the ordinary means of warning of the fact that there was an outbreak of measles on board the vessel. His noble friend then went on to say that it was an unfortunate omission not to fly the yellow flag while the ship was in the harbour. With regard to the share of the responsibility, he could not concur with his noble friend. He was of opinion that the greater portion of the responsibility rested upon the colonial authorities. In reference to flying the yellow flag, that was not required by the regulations when a vessel with measles on board came into a home port, unless there was a special order in council that the yellow flag should be hoisted. Nor was it required in a foreign port unless the quarantine regulations prescribed it. He was not aware that there were any such regulations in Fiji. Directly the *Dido* came into harbour she was boarded by Mr. Layard, the administrator. The captain was on the watch for him, and informed him as he came up to the ship's side, that the doctor wished to see him. The administrator went down into the cabin, and the doctor informed him that there were measles on board.

So that the captain and the doctor took steps to inform the colonial authorities of that fact; but, unfortunately, none of the parties concerned seemed to be aware of the serious nature of the disease when imported fresh among the natives. The Admiralty had informed the doctor and captain that they disapproved of their conduct in not having treated the matter more seriously. The disease was treated by all on board as merely a child's disease. No proper precautions were taken to prevent its communication with the shore, and the consequence was a lamentable loss of life among the natives of the Fiji Islands. The want of precaution seemed to have arisen from ignorance rather than from intentional neglect.'

The fact of the medical officer informing the colonial administrator of the presence of measles on board absolves him from the negligence with which he was in the first instance charged, besides which we have still to hear from the surgeon himself what kind of representation he really did make to the local authorities. It not unfrequently happens that a naval or military surgeon sends in a report throwing out suggestions and urging certain measures to be adopted, and afterwards get blamed for the evil consequences that have arisen through his representations having received no attention from his superior officers.

Cruelty to Animals.

It is somewhat remarkable that the humane British public, which has been recently represented as so dreadfully and universally shocked at the horrors of vivisection, appears to be unaccountably callous to every kind of cruelty that cannot be laid to the charge of medical and scientific men. Quite recently our respected contemporary the *Lancet* drew the attention of their readers to the cruel treatment to which live turtle were subjected during their transit to London, and now it appears that the humanity of public opinion is not so immaculate but that it can tolerate more than one form of cruelty. It appears from the evidence in the case of a young Irish lad who was tried the other day at the Salford Borough Police Court, for torturing a fowl, that the practice was, at any rate a year ago, systematically carried on by a poulterer in Salford. The youth in question was, one day last July, seen by an inspector of police who visited the dealer's premises, to take a live fowl, handed to him by another man, and in spite of its struggles, strip the feathers from the whole of its breast and belly and a portion of the back. The officers were unable then to apprehend the offender, who was only arrested last week in Ireland. The magistrate, who declared that if such a practice were indeed common, it must be effectually stopped, imposed the heaviest penalty the law would allow him to inflict, and sentenced the prisoner to three months' imprisonment with hard labour.

A writer in the daily press well remarks that "this award would scarcely seem too harsh, but for the fact that the sentence is the very same so frequently passed upon men found guilty of cruelly illusing their own wives and children." We readily endorse this well-merited hit at our ultra-humanitarian neighbours. There can be no doubt that our dread of inflicting pain upon the lower animals may be carried too far, and that in our concern for their comfort and humane treatment we may fall short of the duties we owe to our own species. Charity should begin at home, and it is a great shame that the punishment we inflict upon a drunken husband for nearly murdering his wife should be no more than that allowed for cruelty inflicted upon a fowl or a cat.

The Keighley Guardians have been taken into custody and conveyed to York Castle for refusing to carry out the provisions of the Vaccination Act.

Professor Marshall, F.R.S., has been unanimously elected Consulting-Surgeon to the Brompton Consumption Hospital, vice Sir William Fergusson, resigned.

Of the 197 candidates recently examined for the membership of the Royal College of Surgeons, England, only 118 passed to the satisfaction of the Court of Examiners; 28 passed in surgery, and when qualified in medicine will be admitted members of the College. The remainder were referred to their studies for six months.

◆

NOTES FROM OUR EXCHANGES.

Liquor Potassæ in the Treatment of Chlorosis.

A. P. Reid, Professor of Medicine and Clinical Medicine, Halifax Medical College (*The Canada Medical Record*, May, 1876), advocates the use of liquor potassæ in ten minim doses, three times a day, in cases of uncomplicated chlorosis. Its good effects are due to its powerful diuretic action in the elimination of the solid constituents of the urine, thus removing effete matter from the blood, and allowing the recuperative powers of the body fair play.

He gives the particulars of one case, in which its administration was attended with the most marked benefit. There was no recognisable disease of the various organs of the body. Amongst the symptoms present were the following: amenorrhœa, anæmia, the blood being much impoverished, venous hum, anæmic cardiac murmur, general anasarca, which simulated the last stage of Bright's disease, with inability to even sit up in bed. A variety of treatment had failed to effect the slightest improvement. Under the conviction that the blood, in addition to being very watery, was loaded with excrementitious products, and that the debilitated emunctories were unable to remove these impurities from the blood, the liquor potassæ was prescribed. In two days improvement was apparent; in two weeks she was able to sit up, the anasarca having quite disappeared, and in five weeks she was quite restored to health. He mentions the fact that similar benefit was experienced in six other cases, of uncomplicated chlorosis so treated. The fact of its success is worth bearing in mind.

A Case of Ovariotomy.

Dr. R. Stansbury Sutton (*Med. and Surg. Reporter*, April 29th, 1876), reports a very interesting case of the above, the patient being an Irishwoman, a widow, æt. 49, who had borne three children, the youngest of whom at the date of the operation was 18 years of age. In her 47th year the menstrual flow ceased suddenly during one of the periods, in consequence of a severe fright she received. The tumour was first perceived growing in the left side two months after the cessation of the "menses." It rapidly and constantly enlarged for the space of two years. The following were the measurements taken shortly before the operation :—

At umbilicus, around the body, ...	40	in.
Just above umbilicus	41	„
From ensiform cartilage to umbilicus ...	7¾	„
From symphysis pubis to umbilicus... ...	8½	„
From right supra-spinous process of ilium to umbilicus	9	„
From left supra-spinous process of ilium to umbilicus	10	„

The diagnosis was a multilocular ovarian cyst, which the operation proved to be correct. There were three cysts. In the wall of the largest was imbedded a bone resembling a lateral half of the inferior maxillary containing one tooth ; on the inner surface of the cyst wall was a patch of true skin, with a cartilaginous tubercle in its centre, which was surrounded with a sturdy growth of hairs, and in the contained fluid a roll of reddish-brown hair was found. These elements established the dermoid character of the tumour beyond doubt—a matter of considerable interest, as a microscopical examination of the contained fluid demonstrated the presence of the "*ovarian cell" and albumen.* Many gynæcologists question the presence of albumen and the ovarian cell in the fluid of dermoid cysts ; they believe that these are alone found in pure ovarian fluid, and are distinctive of that, and of nothing else. There was nothing remarkable about the operation itself. The first incision was five and a-half inches in length, made in the median line ; this was subsequently enlarged seven-eighths of an inch, terminating just below the umbilicus. The pedicle was of moderate thickness ; the clamp was used in securing it. There were not many adhesions except where the tumour was in apposition with the lower border of the liver, the transverse colon, and the omentum ; the adhesions in these places were very strong.

The case terminated fatally fifty-six hours after the operation. No *post-mortem* was allowed.

◆

Correspondence.

MEDICAL PRACTICE IN SOUTH LONDON.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I beg to enclose a precious document which is being extensively circulated among my patients and others in this neighbourhood. On referring to the "Medical Register" I find that the advertiser is M.B., T.C.D., and L.R.C.S.I. His N.B., that "the above fees are only charged to the working classes," is not true, as to my knowledge they are charged to well-to-do tradespeople, to the detriment of the regular practitioners. I think the authorities of T.C.D. and R.C.S.I. ought to be acquainted with the doings of Mr. George A. Lewis, and enclosing my card,

Remain Sir, yours truly,
NEMO.

THE SURREY SQUARE
PROVIDENT DISPENSARY,
214 OLD KENT ROAD.
Corner of Surrey Square.

Patients are informed that on account of the great number who have availed themselves of the advantages of the above Institution (over 3,000 during the past year), and the number who require to be visited daily, the hours of attendance will in future be as follows :—

Mornings (Sundays and Thursdays excepted), from 11 a.m. to 1 o'clock.

Evenings—Mondays, Wednesdays, and Saturdays—from 7 p.m. to 9 o'clock.

GEORGE A. LEWIS, REGISTERED PHYSICIAN,
SURGEON, ACCOUCHEUR, &c.,
WILL BE IN ATTENDANCE DURING ABOVE HOURS.

Some of the Special Advantages of this Institution are :—

1. Patients, in order to receive attendance, do not require a letter or order. 2. No time is lost by long waiting, as Patients receive immediate attention. 3. The Fees being so small, no deprivation is felt by the working classes. 4. All the best Medicines are provided.

TERMS :—

Advice and medicine for one week, 1s. 6d. Home visitation and medicine for one week, 3s. 6d. Midwifery from 15s., including full attendance and all necessary medicines. Vaccination and Certificate, 1s. 6d.

THE DISEASES OF WOMEN AND CHILDREN RECEIVE SPECIAL ATTENTION.

N.B.—The above fees are only charged to the working classes and their families and must be prepaid. Patients to provide their own bottles, &c.

◆

Medical News.

Royal College of Surgeons of England.—The following gentlemen, having passed the required examination for the diploma, were duly admitted Members of the College at a meeting of the Court of Examiners on the 3rd inst. :—

Bevan, Richard, L.S.A., Redruth, Cornwall.
Boodle, George A., L.S.A., St. John's Wood.
Bullen, Beresford R., Upper Kennington Lane.
Cuming, Charles H., Devonport.
Dowding, Alexander W. W., L.S.A., Ampthill.
Eve, Frederick S., Romford, Essex.
Fabien, Lewis, Trinidad, West Indies.
Gathergood, Benjamin W., L.S.A., Lynn Regis.
Glyn, Herbert A., M.B., Gloucester Street.
Hatch, W. K., M.B., Shrewsbury.
Hume, Frederick N., Meonstoke, Hants.
Mahony, Lawrence F., L.S.A., Dalston.
Paul, Reginald, L.S.A., Langport, Somerset.
Rowbotham, Arthur J., Woolwich, Kent.
Sandwith, Fleming M., Wimbledon.
Stevenson, Leader H., Bexley, Kent.

Royal College of Surgeons, Ireland.—At examinations held on July 25th and following days, the undernamed were admitted Licentiates of the College :—

James Ahern, Joseph Atkinson, John Patrick Barber, John Wm. Beatty, William Joseph Carroll, John Patrick Clarke, William Mayne Clayton, John David Collier, John Conry, James Davidson, John Delahoyde, John Dunbar Dickson, Anthony Doyle, Patrick Dunn, Laurence Finegan, John Flanagan, William John Fraser, John A. Frend, William Hartigan, Henry Stewart Jackson, Hugh Kennedy, William Peter Kirwan, George Reginald Leeper, Michael Macnamara, Jemes M'Mun, Edmund Murphy, Timothy O'Connell, Eugene O'Donovan, Goodwin O'Grady, John Albert O'Meara, John S. Reed, Thomas Russell, John Ryan, George Stoker, Chas. Joseph Trimble, Edward Thomas White, Wm. M'Dowel Wright.

Vital Statistics.—From the Registrar-General's report we learn that during last week 5723 births and 3953 deaths were registered in London and twenty-two other large towns of the United Kingdom. The mortality from all causes was at the average rate of 26 deaths annually in every 1000 persons living. The annual death-rate was 20 per 1000 in Edinburgh, 21 in Dublin, 26 in Glasgow, and 25 in London. The annual rates of mortality during the same period in the other large towns were—Bradford 24, Norwich 23, Brighton 16, Wolverhampton 27, Birmingham 21, Sunderland 22, Portsmouth 22, Sheffield 27, Plymouth 19, Nottingham 36, Liverpool 27, Bristol 23, Leicester 40, Oldham 31, Newcastle-upon-Tyne 26, Hull 30, Manchester 28, Salford 30, and Leeds 36. The annual death-rate from the seven principal zymotic diseases averaged 8·5 per 1000 in these towns, and ranged from 2·9 and 4·3 in Plymouth and Wolverhampton, to 17·9 and 18·4 in Leicester and Nottingham. Scarlet fever continues fatally prevalent in Portsmouth ; small-pox caused 15 deaths in Liverpool, 12 in Manchester and Salford, and only one in London. The deaths referred to diarrhœa in these towns, which in the five previous weeks had steadily increased from 88 to 904, declined last week to 851. The annual death-rate from this disease was equal to 6·0 per 1000 in London, and averaged 6·8 in the nineteen other large provincial towns, ranging from 2·2 and 2·5 in Plymouth and Oldham, to 13·8 and 15·6 in Leicester and Nottingham.

University of London.—The following candidates have passed the first M.B. Examination :—

First Division.

Baddeley, C. E., King's Coll.
Boyd, J. S. N., University Coll.
Clark, C. A. D., St. Bartholomew's.
Collier, M. P. M., St. Thomas's.
Gabb, J. P. A., University Coll.
George, G. A., University Coll.
Heath, W. C., University Coll.
Lory, W. M., St. Bartholomew's.
Matthew's V., King's Coll.
Neale, J. E., University Coll.
Phillips, S. P. University Coll.
Saunders, J. C., St. Bartholomew's.
Sheppard, C. E., St. Thomas's.
Smith, K. R., University Coll.
Stewart, H. D., King's Coll.
Urthoff, J. C., Guy's.
Wainewright, R. S., Guy's.
Whitney, N. S., University Coll.
Williams, D. J. University Coll.

Second Division.

Andrews, W. S., University Coll.
Berry, F. H., Guy's.
Calhane, F. W. S., University Coll.
Dymott, D. F., University Coll.
Faulkner, J. T., Owen's Coll.
Hadden, W. B., Liverpool School.
Jewell, C. C., University Coll.
Jones, R. H., Liverpool School.
Juler, H. E., St. Mary's.
Lendon, A. A., University Coll.
Mackern, G., Guy's.
Manby, H. L., Guy's.
Marsh, J. H., St. Thomas's.
Notley, W. J., Edinburgh University.
Russell, G. H., Guy's.
Salter, J. R., University Coll.
Sheldon, T. S., Guy's.
Tuke, W. S., University Coll.

Excluding Physiology.

First Division.

Meek, J. W., Guy's.

Second Division.

Barker, F. R., St. Thomas's.
Clark, J. R. A., University Coll.
Hughes, R., Owen's Coll.
Shaw, G., Westminster.
Vinrace, J. H., Queen's Coll. Birmingham.
Williams, D., University Coll.

Physiology Only.

First Division.

Blake, W. H., University Coll.
Cuming, C. H., University Coll.
Plumbe, S. T., St. Bartholomew's.

Second Division.

Drysdale, A. E., Univ. Coll., and Liverpool School.
Pickup, W. J., Univ. Coll.
Ryley, J., University Coll.
Smith, H. U., St. Thomas's.

Royal College of Surgeons, Edinburgh.—The following gentlemen have passed their first professional examination :—

Beresford, F. J., Leicester
Gordon, Richard, jun., Sligo
Maclean, Kenneth, Ross-shire
Ryan, Mark F., Kilconly
Thatcher, Chas. H., Edinburgh

The following gentlemen passed their final examination, and were admitted Licentiates of the College :—

Fraser, Peter, Hamilton
Forbes, Duncan, Dumfries
Hamilton, J. A. G., Co. Tyrone
Hardie, Robert, Leith
Hunter, Henry, Co. Derry
Irving, R. W., Blair Athole
Jolly, S. A., Portarlington
MacRitchie, Donald, Inverness
Magill, James, Derry
Maull, Wm., Auchterarder
Nichol, J. T., Newcastle-on-Tyne
Norris, R. Hill, Birmingham
Smith, William, Preston
Willard, Rufus, Illinois

Royal College of Physicians and Surgeons, Edinburgh.—Double Qualification.—The following gentlemen passed their first professional examination during the recent examinations :—

Andrianaly, Madagascar
Christie, J. W., Stirling
Dobson, Arthur, Leeds
Grealy, Joseph, Galway
Hutchinson, J. G., Cumberland
Kennedy, S., County Down
Legat, A. E., South Shields
Leiper, Alexander, Stonehouse
Mason, A. H., Kent
M'Callum, Edward, Edinburgh
Paine, Frank Trevor, Cardiff
Parry, J. H., North Wales
Rajaonah, Madagascar
Reid, R. S., New Zealand
Roberts, A. R., Worcestershire
Service, John, Kilwinning
Simpson, Rbt. Parkyn, Boston
Tanner, L. J., Newman, Cork
Whiteley, E. A., Wakefield
Witz, James F., Tobago

The following gentlemen passed their final examination, and were admitted L.R.C.P.E. and L.R.C.S.E. :—

Badcock, G. S., Brighton
Baker, Jas. Payne, Maidstone
Balbirnie, J. P., Leamington
Blumer, Wm. P., Sunderland
Brander, Edward S., India
Brown, Horatio B., Folkestone
Bull, Joshua Edward, Cork
Calwell, Wm., Ballyreagh
Darutz, Jean A. C., Mauritius
Deacon, Wm. Oliver, Armagh
Dockeray, John A., Rathvilly
Elliott, Jas. May, Dungannon
Fletcher, F. A. C., Yorkshire
Green, Albert, Bradford
Hiffernan, James Eld, Mallow
Kay, Alfred, London
Kirk, Robert, Bathgate
Lord, Frederick, Kent
Lucas, J. H. R. W., Liverpool
M'Glade, James, Kent
M'Kinney, S. B. G., Belfast
Morrison, A., Linlithgowshire
Osburne, Cecil A. P., Cork
Roberts, T. M'Guire, Dublin
Sanctuary, Thos., Dorsetshire
Scott, W. E., Northamptonshire

Metropolitan Hospital Sunday Fund.—At the meeting of the Council of the Hospital Sunday Fund, held at the Mansion House on Thursday week, the following awards were made. It is to be hoped that the Council will another year see their way to exclude many of the special hospitals, or rather private institutions from a fund subscribed for the benefit of hospitals and dispensaries. We contend that petty places devoted to the treatment of the throat, heart, stone, hip diseases for children, dental, &c., should at all events not be classed among hospitals.

General Hospitals: Charing Cross, £816 13s. 4d. ; French, £122 10s. 0d. ; German, £632 4s. 4d. ; Great Northern, £259 14s. 0d. ; King's College, £1,164 3s. 10d. ; London, £2,307 16s. 8d. ; Metropolitan Free, £291 13s. 4d. ; Poplar, £350 0s. 0d. ; Royal Free, £641 13s. 4d. ; St. George's £2,100 0s. 0d. ; SS. John & Elizabeth, £151 13s. 4d. ; St. Mary's, £1,050 0s. 0d. ; Seamen's, £816 14s. 4d. ; the Middlesex, £1,633 6s. 8d. ; University College, £8 62 4s. 9d. ; Westminster, £758 6s. 8d.

Special Hospitals, viz:—(Chest Hospitals.) City of London, for Diseases of the Chest, £700 0s. 0d. ; Hospital for Consumpton, £888 9s. 5d. ; North London Consumption, £239 3s. 4d. ; Royal Hospital for Diseases of the Chest, £116 13s. 1d. ; (Children's Hospitals), Belgrave, £105 0s. 0d ; East London, £235 0s. 0d. ; Evelina, £350 0s. 0d. ; Hospitals for Sick Children, £408 6s. 8d. ; Home for Sick Children and South London Dispensary for Women, £59 10s. 0d. ; Hospital for Hip Diseases in Childhood, £140 0s. 0d. ; North Eastern, £140 0s. 0d. ; Victoria, £190 7s. 1d. ; (Lying-in Hospitals.) British, £58 6s. 8d. ; City of London, £58 6s. 8d. ; General, £87 10s. 0d. ; Queen Charlotte's, £151 13s. 4d. ; (Hospitals for Women.) Hospital for Women (Soho Square), £175 0s. 0d. ; Hospital for Women and Children, £41 13s. 4d. ; New Hospital for Women, £110 16s. 8d. ; Royal Infirmary for Diseases of Women and Children, £116 13s. 4d. ; Samaritan Free, £327 16s. 8d.

Other Special Hospitals: Cancer, £70 0s. 0d. ; London Fever Hospital, £262 10s. 0d. ; St. Mark's (Fistula), £175 0s. 0d. ; National, for Diseases of the Heart, £70 0s. 0d. ; Lock Hospital, (Female), £175 0s. 0d. ; Lock Hospital (Male), £163 6s. 8d. ; Hospital for Diseases of the Nervous System, £116 13s. 4d. ; National, for Paralysis and Epilepsy, £303 6s. 8d. ; Royal London Ophthalmic, £347 2s. 11d. ; Royal South London Ophthalmic, £35 0s. 0d. ; Royal Westminster Ophthalmic, £93 6s. 8d. ; Western Ophthalmic, £29 3s. 4d. ; National Orthopædic, £75 16s. 8d. ; Royal Orthopædic, £40 16s. 8d. ; Hospital for Diseases of the Skin, £35 0s. 0d. ; St. Peter's, for Stone, £35 0s. 0d. ; Hospital for Diseases of the Throat, £102 18s. 0d. ; London Homœopathic, £250 16s. 8d. ; Dental, £71 3s. 4d. ; National Dental, £5 16s. 8d.

Convalescent Hospitals: Metropolitan Convalescent Institution, £700 0s. 0d ; Mrs. Gladstone's, £233 6s. 8d. ; Mrs. Kitto's, £30 6s. 8d. ; Mrs. Marshman's, £53 13s. 4d. ; Mrs. Rusher's, £46 13s. 4d. ; Seaside Convalescent Hospital (Seaford) £58 6s. 8d. ; St. Andrew's Convalescent Home, Clewer, £156 11s. 4d.; St. Mary Magdalene Convalescent Home, £23 6s. 8d.

Cottage Hospitals: Beckenham, £35 0s. 0d. ; Bromley, £24 10s. ; Wimbledon, £25 13s. 4d.

Dispensaries: Battersea (Provident), £12 16s. 8d. ; Bloomsbury, £47 16s. 8d. ; Camberwell (Provident), £58 6s. 8d. ; Chelsea, &c., £52 10s. 0d. ; City, £99 3s. 4d. ; Clapham (General), £46 13s. 5d. ; Dulwich, £17 10s. 0d. ; Eastern, £32 13s. 4d. ; Farringdon, £50 3s. 4d. ; Finsbury, £58 6s. 8d. ;

Holloway and North Islington, £93 6s. 8d.; Islington, £58 6s. 8d.; Islington and North London (Provident), £10 10s. 0d.; Kensington, £58 6s. 8d.; Kilburn, £58 6s. 8d.; London, £14 0s. 0d.; Margaret Street Infirmary for Consumption, £35 0s. 0d.; Metropolitan, £54 16s. 8d.; North West London (Children) £18 13s. 4d.; Notting Hill (Provident), £44 6s. 8d.; Paddington (Provident), £17 10s. 0d.; Portland Town, £43 3s. 4d.; Provident Medical Institution, £21 0s. 0d.; Public, £60 13s. 4d.; Queen Adelaide's, £46 13s. 4d.; Royal General, £54 16s. 8d.; Royal Kent, £122 10s. 0d.; Royal Maternity Charity, £29 3s. 4d.; Royal Pimlico, £75 16s. 8d.; Royal South London, £93 16s. 8d.; SS. George's & James's, £59 10s. 0d.; St. George's, Hanover Square (Provident), £67 13s. 4d.; St. John's Wood (Provident), £40 16s. 8d.; St. Marylebone, General, £58 6s. 8d.; St. Pancras & Northern, £52 10s. 0d.; SS. Paul & Barnabas, £52 10s. 0d.; South Lambeth, £40 16s. 8d.; Stamford Hill, &c., £24 17s. 10d.; Surrey, £35 0s. 0d.; Tower Hamlets, £52 10s. 0d.; Westbourne (Provident), £29 3s. 4d.; Western, £81 13s. 4d.; Western General, £116 13s. 4d.; West Ham & Stratford, £44 19s. 10d.; Westminster General, £64 3s. 4d.

Institutions: Establishment for Gentlewomen, £175 0s. 0d.; Royal Sea Bathing Infirmary (Margate), £315 0s. 0d.; National Sanatorium (Bournemouth), £145 16s. 8d.; National Hospital for Consumption (Ventnor), £116 13s. 4d.; St. George's, Hanover Square (Provident) Dispensary, amount deducted in error in 1875, owing to incorrect information sent to the Committee of Distribution, £32 4s. 10d.

Indian Medical Service.—The following gentlemen were successful at both the London and Netley examinations recently held, having passed through a course of instruction at the Army Medical School, Netley:—

	Marks.		Marks.

National Orthopædic Hospital of Ireland.—We hear that an Orthopædic Hospital has at last been established in Dublin. We were aware that for more than a year past such an institution was in contemplation, the delay being caused by want of suitable premises, which difficulty has now been overcome. The new institution is under the auspices of Mr. Porter, Surgeon to Her Majesty the Queen in Ireland, and Mr. Smyly, Surgeon to the Lord-Lieutenant, as consultants. Mr. Lambert H. Ormsby, Surgeon to the Meath Hospital, and author of "Deformities of the Human Body," being Surgeon in charge.

◆

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials,* and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention t this rule.

Erratum.—In Dr. Griffith's article on "Hydrocyanic Acid" in our last issue some errors have crept in. The author desires to mention that in the transcript of Dr. West's formula the quantity of *Mist. Amygdalæ* should have been ℥i., not ʒi.

A Taste for Linen.—Last week a bullock, on the Commons, Coleraine, ate two shirts, a lady's night-cap, and six gentlemen's collars, from a washerwoman. An extraordinary circumstance connected with the affair is this:—The bullock was killed in the evening of the day, and five of the collars were found in the stomach, with scarcely an impress of a tooth on them. They were returned to the owner, and have since been washed and made up, and look well, after being secreted in the stomach of the bullock for half-a-day.

Dr. L.—Your suggestion received with thanks; the gentleman most immediately interested is on the Continent at present, and will doubtless reply on his return.

Dr. Elliot.—The prescription to which you refer in Dr. Handsel Griffith's last communication was an error. You will find the rectification in an erratum this week.

Mr. Harston.—Sorry we cannot find space for your communication; it is scarcely suitable.

Pegum.—On August 2, at Carrigaholt, co. Clare, of Fever, Thomas Pegum, L.R.C.S.I., L. & C.M.K.Q.C.P.I.

Rainy.—On August 6, at Woodside Place, Glasgow, Harry Rainy, M.D., aged 83.

Tindall.—On July 31, at Abbotsford Place, Glasgow, David Tindall, L.F.P.S.G.

Tomlinson.—On August 3, at Preston, Watson Tomlinson, L.R.C.P.Ed., aged 29.

IRISH POOR-LAW INTELLIGENCE.

BALLINA SESSIONS.

CHARGE OF "UNLAWFULLY SELLING POISON."

SUB-INSPECTOR SOMMERVILLE *v.* JOHN MACAULAY.

The charge was that defendant did on the 17th September last unlawfully sell poison, to wit, a portion of tartar emetic, for that whereas the wrapper or cover in which the said poison was contained was not labelled with the name of the article, nor with the word 'poison,' nor with the name of the poison; and whereas on the sale of the said poison the seller did not make, or cause to be made, an entry in a book to be kept for that purpose, giving date of sale, name and quantity of the article sold, and the purpose for which it was stated it was required, and to which the signature of the purchaser was not affixed."

On 17th September a Mrs. Beirne, desiring to give "cream of tartar" to her children, sent a shop assistant, named Neary, to Mr. Macaulay, who sells medicines and poisons it appears in the next street; Mr. Macaulay, through his servant, gave one ounce of what was understood to be cream of tartar, for which the usual price was paid. The messenger returned, and Mrs. Beirne, believing that the article was what she sent for, administered it to her children, and partook of some herself. The children became immediately so sick, and their lives so evidently in danger, that Dr. Nolan was at once called in, and owing to his skill and prompt measures, under Providence, the lives of all concerned were saved. The defendant had no licence to sell poisons, and no authority to sell them, and undertaking their sale he neglected altogether the provisions of the Act of Parliament, wisely framed for the protection of the public.

Mr. Bourke—My learned friend is departing altogether from the charge, which is that defendant did not label a certain article which he sold.

Chairman—I beg your pardon. The charge is that defendant did "unlawfully sell poison." Mr. Jordan's observations are quite pertinent to that.

Mr. Bourke—Then I say that it is no offence to sell poisons, and no Act of Parliament is violated by their sale.

Mr. Jordan—I say that a person selling poisons must comply with certain rules and regulations provided by the statute, and that if he even have a licence, that would not justify him in dispensing with the precautions necessary to be taken. The case appears to me to be one of vital importance to the public, and in the public interest the Attorney-General has directed this case to be prosecuted, to save the people from the consequences which must follow when the sales of poisons is undertaken by ignorant and unskilled people.

Chairman—Do you not think it necessary to explain why the case has been allowed to lie over for ten months?

Mr Jordan—With regard to that, it appears that some correspondence took place by which time was lost, and that then Mrs. Beirne, finding that her children's lives were saved, became unwilling to prosecute the vendor of the poison, and it was not till June that a prosecution was decided on.

Chairman—You are aware that proceedings under the Petty Sessions Act, except in some particular cases enumerated in it, must be brought within six months after the commission of the offence.

Mr. Bourke—If the Act of Parliament says that no proceedings can be taken after six months, I would ask you not to go into the case.

Chairman—The Attorney-General gave directions in this case in June last, and it may be possible he overlooked this point. We will hear the evidence, which has been brought here at much expense, and then formally adjourn the case, in order to take the opinion of the Law Adviser.

Mr. Bourke—In point of fact the Court has no jurisdiction.

Chairman—That is my impression.

Mrs. Jane Beirne to Mr. Jordan—I recollect sending to Mr. Macaulay's before Christmas for an ounce of cream of tartar; what was brought back I gave to the children, and I saw no difference in the colour. I put it in spring water. I gave it to them between eight and nine o'clock, as they were going to bed.

Chairman—In how much water did you put it? In five noggins. I gave it first to the eldest boy, who took about two mouthfuls; I then gave it to the second boy, who said he found a queer taste on it, and he only tasted it. I then took one or two small sups of it myself to show that there was nothing at all in it; the fourth and fifth children then took some; the third child was then asleep.

Mr. Jordan—Were the children up to this in good health and spirits? I remarked nothing wrong with them?

How long had they taken this when they became unwell? It was their father detected it first.

Chairman—Did you yourself see them? Yes, in about an hour after.

What was wrong with them then? They got a wrenching of the stomach.

All of them? Yes. They had beef for dinner, and I thought it was diseased meat they had eaten, as there was some in the town at the time.

Mr. Jordan—Were the children still unwell? Indeed they were. The doctor examined them and saw how they were affected; he asked what they had eaten, and I told him; he asked where the meat was got, and being told, he said he had had some of the same himself, and that was the best beef in the town. He asked did they get anything else, and I told him I had given them a drink of cream of tartar; he told me to show him the vessel, and having stirred it round, he said I had the "children killed."

How long did the children continue ill? They were up the next day.

Did the doctor give them anything to relieve them? He said they had taken tartar emetic, and he gave them strong tea and hot brandy.

Chairman—Were you unwell yourself? I was.

Did you take the same remedy the children got? I took nothing at all.

Dr. Nolan examined—I was called in to see the children of Mr. Beirne in September last.

What state were they in? They were very sick;

vomiting very much; scarcely a pulse; teeming with a cold perspiration, and cramped.

All these symptoms were indicative of an irritant poison? They were. I asked where was the poison, and was shown a mug, and having stirred what was in it, I said to Mrs. Beirne she had the children poisoned. I then got some strong tea and brandy, and gave it to them, and went to the hotel for soda water, as one of them was in a collapsed condition. They were very uneasy about the children, and I said it would be well to ascertain what they had taken, and I told Mr. Beirne to get a bottle, and I would send what remained in the mug to Dr. Cameron for analysis. He got a soda-water bottle, and when washed I put the matter into it; he sealed it and I took it away.

Chairman—Is there not a marked difference between cream of tartar and tartar emetic? The former is easily soluble, the latter not so.

Mr. Bourke—Would not these effects be produced by an overdose of cream of tartar? It is not very likely.

Chairman—What quantity of cream of tartar would produce the effects you describe? No quantity. It might act as a purgative, but would not even sicken. The vomiting is an effort of nature to eliminate the poison.

Mr. Bourke—Would not a large quantity of cream of tartar produce vomiting? I have never known it to do so.

Mr. Jordan—What these children got would not produce vomiting if cream of tartar! No. Six grains of tartar emetic would poison a person.

Chairman—There was an ounce divided into ten parts. Some of the children must have taken sixty grains.

Dr. Nolan said there was less danger in taking this quantity than the smaller quantity, as it was easily eliminated. If you gave a dog forty grains of arsenic it will not kill it; give it six grains and it will kill it.

Dr. Charles A. Cameron sworn—Did you examine the contents of the bottle? I did.

What did you ascertain it contained? Tartar emetic. I kept the bottle for a considerable time. I always keep the specimens sent to me till they are disposed of, and in this case I wrote to Dr. Nolan, asking him if any proceedings were to be taken in reference to the matter; he wrote back to say that there would be no prosecution, as the parties declined to prosecute. In March last, in my report to the Grand Jury, I sent forward Dr. Nolan's note explaining why there was not a prosecution, as the matter came before me officially. I kept the bottle till June, then having to go to London, I had to clear away a number of things, and I recollect emptying this bottle with my own hands.

Chairman—For all you know the letter and box went by the same train?

Dr. Nolan (recalled)—Yes. I labelled the bottle, "supposed to be cream of tartar."

Chairman—Was there anything in connection with the bottle to lead you to conclude it was the same that was sent by him? There was. I got his letter that morning, saying he had forwarded the box, and then when I opened the box I found it to correspond with the letter. Then there was the word "Ballina" on the label, and on the whole I have no doubt it was the box sent by Dr. Nolan.

What did the bottle contain? Water and tartar emetic.

That you have no doubt about? Oh, not the slightest. I satisfied myself that the bulk, if not the whole, of the article was tartar emetic, but I will not swear there may not have been some cream of tartar.

Chairman—Did you take a note of the analysis in your book? Yes, and I have an extract from my laboratory book here. [Extract read, stating that on 19th September witness received from Dr. Nolan, workhouse, Ballina, a soda water bottle containing a light powder, given to some children as cream of tartar, but which proved to be tartar emetic.]

The Chairman went over the evidence, and Mr. Jackson and he agreed that there could not be a reasonable doubt about the identity of the bottle. The only difficulty in the case was the six months elapsing before it was brought.

Mr. Bourke—I now ask Mr. Jordan what charge does he bring against my client?

Mr. Jordan—It is very plain and intelligible—that he unlawfully sold that which the law says he should not sell.

Chairman—The onus is on you, Mr. Bourke, to produce the book in which is the entry of this sale, if suc book there be.

Mr. Bourke—Do you contend here that Mr. Macaulay cannot sell tartar emetic without being duly licensed?

Mr. Jordan—My contention is, that Mr. Macaulay, or other trader, cannot sell poison unless he complies with certain requirements pointed out by the Act of Parliament.

Mr. Bourke—Is a license one of these?

Mr. Jordan—No.

Mr. Bourke—Then you commenced with that.

Mr. Jordan—Yes, I said that even if he had a license it would not excuse him for selling poison while he neglected the requirements provided by the act.

Mr. Bourke—Well we have got rid of the license.

Mr. Jordan—There are several conditions required, none of which have been complied with.

James Loftus, servant of Dr. Nolan, here came in, and being sworn, said he delivered a box at the railway station, for his master, in the usual course of his business paying the carriage of it.

The case for the Crown closed here.

Mr. Bourke then submitted that the case was outside the jurisdiction of the court, as the proceedings should have been taken in six months from the date of the occurrence.

The Chairmen said the court fully concurred with Mr. Bourke in that, and intended placing it before the Law Adviser with a statement of the facts of the case. The evidence was quite clear that it was tartar emetic that was given, but while this was so Mr. Macaulay was, at the same time, entitled to his rights.

Mr. Bourke said he could not hope to disabuse the mind of the court as regards that, but he would show that it was not the intention of his client to evade the Act of Parliament, and that it was not necessary that he should have any certificate or special qualification to authorise him to sell poison, if he did sell any. Mr. Macaulay's statement was this, that he bought this article as cream of tartar from a respectable druggist; that he kept in a box properly labelled, and that it was from this box Mrs. Bierne was supplied.

Alexander McDonnell examined by Mr. Bourke—I am in the employment of Mr. Macaulay: I recollect Patt Neary coming into the shop and asking for cream of tartar; there were cream of tartar and tartar emetic in the shop; the latter was in a bottle, and labelled "tartar emetic, poison;" the other was in a drawer, and had also a label on it. I went to the drawer, and supplied him out of it.

Do you remember selling cream of tartar frequently? Yes, before this, not since.

Chairman—You often sold cream of tartar before—did you on any occasion make an entry in a book? Sometimes.

Then it was merely by chance. Did you ever sell tartar emetic? Yes.

How often? I cannot say. About half a dozen times.

What was the largest quantity? A quarter of an ounce.

The Chairman said that the Act of Parliament dwelt with the sales of poison, and required of persons selling poison they should label the quantities sold, make entries &c. In this case it was not a poison that was asked for, nor was it a poison that was intended to be given, and, therefore, the label and other precautions provided for in the case of the sale of a poison did not seem called for or necessary. It was plain from this that the case was one about which there was considerable difficulty and doubt.

Mr. Jordan said that it may not have been intended to sell poison; but the Act of Parliament did not deal with intentions, but with facts, and a poison having been sold, the requirements of the Act of Parliament should have been attended to, in order to make the sale a legal one.

Chairman—I merely give my opinion that the case is not one of those contemplated by the Act. This view of it has occurred to me, and it is worthy of consideration. Cream of tartar was asked for, and in mistake tartar emetic was given.

Mr. Macaulay asked to be allowed to make an explanation. He said that tartar emetic was only kept in small quantity, in a bottle apart by itself, and duly labelled, while the cream of tartar was in one of a nest of drawers four yards away, and the witness for the crown proved that it was out this drawer the article he got was taken. He got the cream of tartar in a hundredweight from a druggist in Dublin, and it was put in the drawer just as he received it.

Chairmen—I dont believe that state of facts. I believe your man, by mistake, went to the bottle instead of to the drawer.

Mr. Macaulay—I wish to have Neary examined again.

Neary was recalled, and he stated that McDonnell went to a drawer, not to a bottle.

Chairman—Then how do you account for the tartar emetic being in it?

Mr. Macaulay—Some of my boys through carelessness must have thrown some in.

Mr. Jordan—This is quite in keeping with my statement that the lives of her Majesty's subjects are endangered by drugs and poisons being vended by unskilled and careless persons.

McDonnell was recalled, and in reply to the Chairman said the tartar emetic never was in a drawer to his knowledge.

Was it changed from the drawer to a bottle since Sept? Not to my knowledge. The goods I sold came from the same party in Dublin.

From where did you take what you gave Mary Lacken? From the small drawer, if that satisfies you, in case I gave it at all.

Chairman—The conclusion we have come to is this, that this man did give tartar emetic for cream of tartar, and the gravity of that mistake is too great for language.

The case was then adjourned for a fortnight, in order that the opinion of the Law Adviser may be obtained on the points raised.

THE LATE DR. ARMSTRONG, M.D., OF COLLOONEY.

A MONUMENT has been erected in the Collooney burying ground to the late Dr. Armstrong. It is made of limestone, finely cut, and ornamented, standing ten feet high. The middle slab is finely polished, black, and smooth as marble, and the inscription is truly touching. It is—

"William Armstrong, Medical Officer of Collooney district, died on Friday, April 16, 1875, of fever, taken in the faithful and fearless discharge of his duty, aged thirty-six years." This monument is erected to his memory by many friends who knew and loved him well.

The grave is surrounded by a cut stone base, to be surmounted by an iron railing.

◆

QUESTION AS TO A CORONER'S WARRANT.

Mr. JUSTICE BARRY sat in the Queen's Bench Office to hear an application in the case of the Queen v. Mary M'Gurk.

Mr. Ulick Bourke applied for a *habeas corpus* to bring up Mary M'Gurk, who is at present in Omagh jail, charged on suspicion of having by poison caused the death of her step-son, Peter M'Gurk, of Amolis, in the month of May last. It appeared that the coroner for the district held an inquest on the body of the deceased, and adjourned it pending the analysis by Professor Hodges, of Belfast, of the deceased's body. Pending his report Mary M'Gurk was remanded by the magistrates from time to time, the last remand expired on the 13th of July. Upon the same day the coroner (Mr. W. Oliver Orr) issued a warrant under which the woman was arrested, the terms of the warrant being to keep her in custody "till discharged in due course of law." Counsel submitted that the coroner had no jurisdiction to issue any warrant at all till the inquisition was found, and that the writ of *habeas corpus* should therefore be granted. The delay in completing the inquest was not the fault of Mary M'Gurk, but of those who had charge of the proceedings.

Mr. Justice Barry said he would grant a conditional order, to be served on the governor of Omagh jail, the coroner, and the crown solicitor.

DEATH BY POISON.

HENRY HANDER, a medical student, aged 22, the son of Mr. Hander, photographic artist, Patrick Street, Cork, came by his death on Tuesday week under melancholy circumstances. His father was preparing a bath for photographic purposes, and the young fellow went into the room and swallowed a quantity of cyanide of potassium. Medical assistance was immediately summoned, and though the stomach-pipe was applied all efforts proved futile, and he died in a few hours.

ADDRESS AND PRESENTATION TO DR. W. F. SWEENIE.

ON the 27th ult., a deputation from the friends of Dr. Sweenie, Newtowncunningham, wated on that gentleman at his residence, and presented him with an address, accompanied by a gold watch and chain, and a cheque for £100.

A FOSSIL ELK FOUND IN TYRONE.

A FEW days since a farmer named Carbarry, residing near Carnteel, Tyrone, discovered buried in a bog, and covered with water, about five feet from the surface, the complete skeleton of an elk. The horns, which measure between four and five from tip to tip, have sixteen antlers. All the bones are in a most perfect state, not a single tooth being missing from the jaws.

◆

A SUICIDE of a most distressing and painful nature has been committed at Ferbane, in the King's County. Dr. Smyth, medical officer of that district, who for some days previously suffered from hypochondria, took a large dose of strychnine which terminated fatally shortly afterwards. At first it was supposed that the unfortunate deceased died of heart disease, but subsequently part of the fatal draught was discovered in his chamber. The deceased leaves a large family to mourn his unexpected and untimely decease.

LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR THE MONTHS OF JULY, 1876.

JULY 1st.—Sproulle, Oliver William, Moville, co. Donegal, M.B. 1876, and Lic. Surg. 1876, Univ. Dub.

1st.—Mara, Wm. Francis, Athy, co. Kildare, Lic. 1867, and Lic. Mid. 1875, R. Coll. Surg. Irel., Lic. K. Q. Coll. Phys. Irel. 1875.

1st.—Geoghegan, Francis Meagher, 55 Stephen's Green, Dublin, M.D. 1876, and M.Ch. 1876, Q. Univ. Irel.

1st.—Blake, Richard Marlay, Bridge House, Quam, co. Galway, Lic. R. Coll. Surg. Irel. 1875, Lic. 1876, and Lic. Mid. 1876, K. Q. Coll. Phys. Irel.

3rd.—Donovan, Justin F., 52 King Street, Cork, M.D. 1876, and M.Ch. 1876, Q. Univ. Irel.

3rd.—Maguiness, Robert Maude, the Rectory, Dromore, co. Tyrone, M.B. 1876, and Lic. Surg. 1876 Univ. Dub.

3rd.—Gorman, Charles, 70 Lower Mount Street, Dublin, M.B. 1876, and Lic. Surg. 1876 Univ. Dub.

5th.—Hamilton, Thos Kinley, Drumcree, Portadown, co. Armagh, M.B. Univ. Dub. 1876, Lic. R. Coll. Surg. Irel. 1876.

6th.—Twigg, Geo. Despard, 25 Waltham Terrace, Blackrock, co. Dublin, Lic. R. Coll. Surg. Irel. 1875, Lic. 1876, and Lic. Mid. 1876, K. Q. Coll. Phys. Irel.

6th.—Poole, Jonas Sealy, 15 Lower FitzWilliam Street, Dublin, M.D. 1876, and M.Ch. 1876, Univ. Dub.

4th.—Benson, Arthur Henry, 42 FitzWilliam Square, Dublin, Lic. R. Coll. Surg. Irel. 1874, and Lic. Mid. R. Coll. Surg. Irel. 1876, M.B. Univ. Dub. 1876.

10th.—Lane, John, Donoughmore, Coachford, co. Cork. Lic. in Medicine 1875, and Lic. Surg. 1876, Univ. Dub. M.B. Univ. Dub. 1876.

11th.—Cranston, Wm., Ballybay, co. Monaghan, Lic. R. Coll. Phys. Edin. 1875, Lic. R. Coll. Surg. Edin. 1875.

11th.—Lambert, William Rutherford, Moor Park, Athenry, co. Galway, M.B. Univ. Dub. 1876.

12th.—Laffan, George, Glemrin House, Farrenferris, co. Cork, M.D. 1876, and M.Ch. 1876, Q. Univ. Irel.

14th.—Middleton, John Jameson, Mullingar, co. Westmeath, Lic. R. Coll. Surg. Irel. 1875, Lic. K. Q. Coll. Phys. Irel. 1876.

14th.—Good, Charles, Dromors, Mallow, co. Cork, M.D. 1876, and M.Ch. 1876, Q. Univ. Irel.

14th.—Fullerton, Richard, Victoria Street, Armagh, M.B. 1876, and Lic. Surg. 1876, Univ. Dub.

18th.—Coates, William, Portumna, co. Galway, M.D. 1876, and M.Ch. 1876, Q. Univ. Irel.

18th.—Corcoran, Laurence, Enniscorthy, co. Wexford, M.B. 1875, and M.Ch. 1876, Univ. Dub., Lic. Mid. K. Q. Coll. Phys. Irel. 1876.

18th.—Barcroft, Penrose John, 8 Tivoli Terrace, Kingstown, co. Dublin, Lic. R. Coll. Surg. Irel. 1874, Lic. 1876, and Lic. Mid. 1876, K. Q. Coll. Phys. Irel.

19th.—Falvey, John Joseph, Tralee, co. Kerry, Lic. R. Coll. Surg. Irel. 1876. Lic. Apoth. Hall. Dub. 1876.

19th.—Bennett, Charles Henry, the Rectory, Leap, co. Cork, M.D. 1876, and M.Ch. 1876, Q. Univ. Irel.

20th.—Sampson, Henry Albert, Williamstadt, Scariff, co. Clare, Lic. R. Coll. Surg. Irel. 1875, Lic. 1876, and Lic. Mid. 1876, K. Q. Coll. Phys. Irel.

21st.—Pedlow, James, Union Infirmary, Belfast, M.D. 1876, and M.Ch. 1876, Q. Univ. Irel.

21st.—Collins, Frederick H., Frankfort House, Dundrum, co. Dublin, M.D. 1876, and M.Ch. 1876, Q. Univ. Irel.

22nd.—Wall, Edmund Aloyisius, Ballyguin, Carrick-on-Suir, co. Waterford, Lic. R. Coll. Surg. Irel. 1876, Lic. 1876 and Lic. Mid. 1876, K. Q. Coll. Phys. Irel.

22nd.—Smallman, Benjamin Franklin, Portarlington, Queen's co., Lic. R. Coll. Surg. Irel. 1875. Lic. 1876, and Lic. Mid. 1876, K. Q. Coll. Phys. Irel.

24th.—Marks, Edward George Keighley, 26 Hatch Street, Dublin, Lic. R. Coll. Surg. Irel. 1875., M.D. 1876, and M.Ch. 1876, Q. Univ. Irel., and Lic. Mid. K. Q. Coll. Phys. Irel. 1876

24th.—Dundon, Michael, Barnakyle, Patrick's Well, co. Limerick, M.D. 1876, and M.Ch. 1876, Q. Univ. Irel.

24th.—Gregg, Francis Bland, Church Street, Wicklow, Lic. Apoth. Hall Dub. 1874.

25th.—Moorhead, George Alexander, Tullamore, King's co., Lic. R. Coll. Surg. Irel. 1875, Lic. 1876, and Lic. Mid. 1876, K. Q. Coll. Phys. Irel.

27th.—Fleming, Thomas, Croom, co. Limerick, Lic. Apoth. Hall. Dub. 1859.

28th.—Corbett, Joseph Edward, 12 Clare Street, Lic. R. Coll. Surg. Irel. 1875.

29th.—Peyton, Jones Lloyd, County Infirmary, Roscommon, M.B. 1876, and Lic. Surg. 1876, Univ. Dub.

29th.—Charlton, George Robert Deighton, Clonmacnoise, Shannon Bridge, King's co., Lic. R. Coll. Surg. Irel. 1876, Lic. 1876, and Lic. Mid. 1876, K. Coll. Phys. Irel.

ON THE SCIENTIFIC AND EMPIRICAL INVESTIGATION OF EPILEPSIES.

By J. Hughlings Jackson, M.D., F.R.C.P.,

Physician to the Hospital for the Epileptic and Paralysed, and to the London Hospital.

CHAPTER IX.—*Unilaterally beginning Convulsion.*

In the last chapter we spoke of unilaterally beginning convulsion merely in order to illustrate the method of investigation of Epilepsies in general. We now consider this class of cases in detail.

They are in our definition of the term Epilepsies. They are, I consider, the results of Discharging Lesions beginning in subordinate nervous centres—viz., in the convolutions which are near to the corpus striatum. They are, as has been repeatedly stated, the mobile counterparts of cases of that unilateral paralysis which depends on "destroying lesion" of the corpus striatum. The rule is that these fits begin in those *parts* which *suffer most* in cases of hemiplegia—(1) hand, (2) face, or tongue, or both, (3) foot. This is an illustration of the Law of Dissolution. For both in hemiplegia and in these convulsions the parts which suffer first and most are those which have the most varied uses—that is, parts in the order above given. The seizures which begin in the hand are the mobile counterparts of those cases of hemiplegia in which the arm suffers more than the leg. These are the commonest cases of hemiplegia and of unilaterally beginning convulsion. The fits which begin in the face are the analogues of those cases of hemiplegia in which there is a complication of aphasia. (In the convulsion there is stoppage of speech at the onset, and speech may be left temporarily impaired when the discharge is over.) This is the next commonest corresponding pair of cases. Fits which begin in the foot are the analogues of those cases of hemiplegia where the paralysis affects the leg most. This pair is least common.

We see that the order of *frequency* in which parts suffer also illustrates the Law of Dissolution. Fits beginning in the hand are commonest; next in frequency are those which begin in the face or tongue, and rarest are those which begin in the foot. The law is exemplified in details. When the fit begins in the hand, the index finger and thumb are usually the digits first seized; when in the face, the side of the cheek is first in spasm; when in the foot, almost invariably the great toe. These facts are very significant.

It is very interesting that Ferrier's independent researches confirm the general principle regarding the modes of onset of these convulsions so far as experiments on lower animals can be supposed to be comparable with the experiments disease makes on man. (The parts which have the most varied uses will not be the same in each animal.)

The following general remarks will show how the mode of onset of convulsive seizures illustrates the law of dissolution :—

In this group of fits the spasm "prefers," so to speak, to begin in those parts which have the more voluntary uses; in other words, in those parts which have the more leading, independent, separate, and varied movements; in other words still, in those parts the movements of which are last acquired ("educated"). In strict physiological definition, a voluntary part—the hand, for example—is one which has the greater number of *different* movements at the greater number of *different* intervals; (a) shortly, the more "varied" uses. An automatic part—the chest, for example—is one which has the greater number of more nearly like movements at the greater number of more nearly equal intervals; shortly, the more "similar" uses.

(a) It will be seen that the definition takes count of what I have called Time Co-ordination. There is a Melody of movement as well as a Harmony of movement.

That convulsions which begin in the hand begin in most cases in the thumb and index-finger—in the most "voluntary" parts of the whole body—is a very significant thing. The thumb and index-finger are the most voluntary or specialised parts of the body; they have the most varied uses. The thumb in man has a distinct flexor longus pollicis. In the *Anthropomorpha*, Huxley ("The Anatomy of Vertebrate Animals") says: "The *flexor pollicis* is more or less closely connected with the *flexor communis perforans*, or with that part of the muscle which goes to the index digit." On the intellectual importance of this muscle Duchenne insists strongly. "En somme, ces faits cliniques demontrent que le long fléchisseur du pouce est l'un des muscles qui sont essentiellement destinés, chez l'homme, aux usages manuels les plus delicats; à tenir et à conduire la plume, le crayon, le pinceau, l'aiguille, &c.; qu'il aide, en un mot, à l'execution des travaux manuels qui sont à la hauteur de son intelligence supérieure" ("Physiology of Movements," p. 251). And in his work on "Electrisation," he says that when the small muscles of the thenar eminence are atrophied, the hand loses its distinctive human character and approaches that of the monkey. The thumb in the monkey is less specialised than in man. If, then, we discover in a monkey the homologue of the centre discharged in man causing fits beginning in the thumb and index-finger, we shall expect from *its* discharge a fit of a less special kind; for example, not a fit beginning in the animal's pollex, but more likely one beginning in the whole of its five comparatively little differentiated digits at once, if not in the whole arm.

It is not supposed that there are abrupt demarcations betwixt the two kinds of movements. Movements of the shoulder (intermediate betwixt the arm and the thorax) may be considered as "voluntary" when compared with those of the chest, and automatic when compared with those of the forearm; they are more "varied" than the movements of the chest, and more "similar" than those of the forearm.

An automatic part may possibly be more *often* in movement than a voluntary part, and thus it may in a sense be said to have more movements. But we are speaking of numerous *different* movements. The numerous movements of an automatic part are often but repetitions of one kind of movement in different degrees, or the persistence of one movement, or of several allied, movements. Thus, the muscles of the spine are always in action except in sleep (I am not here referring to mere tone of muscles). But the movements of these muscles when most varied, as in walking, are comparatively little varied; in standing or in sitting there is scarcely any variation in their action; there is little more than one continuous "tetanoid" contraction. Moreover, what is just as important, when in their most varied action there are fewer distinct intervals; indeed, the movements glide into one another. But there are parts which have fewer variations in their movements than even the muscles of the back. Indeed, the ciliary muscle has but one kind of movement, although an infinite number of degrees of that movement. (*a*)

It is, however, granted that convulsion may begin in any part of the region which is paralysed in hemiplegia, for example, in the shoulder, thigh, &c. I speak in this chapter of the cases which are most common. It is a very important matter in the physiology of epilepsies that the spasm "prefers" the parts which have the most varied uses. We saw (Chapter v, p. 421, May 19, 1875) that the parts whose muscles are represented in the greater number of *different* movements would be represented by the greater *quantity* of grey matter.

Spencer has pointed out that the quantity of grey matter in an animal's nervous system varies not so much with the size of its muscles as with the complexity of its movements; or we may put the principle in more detail, that the quantity of grey matter varies not so much with the size of the muscles of a part as with the number of different movements of that part. Thus the small muscles of the hand will be represented by much more grey matter in the highest centres than will be the large muscles of the upper arm, because they serve in more numerous different movements. It is equally obvious that the larger quantity of grey matter representing numerous *different* movements must be made up of a great number of separate parts. Each movement, so far as it differs from all others, must have so far special representation in the nervous centre. Greater differentiation of function implies greater physical separation. There must be separate representation, however little different the movement may be from other movements, and however much of it may be a re-co-ordination of other movements. So far as there is a degree of independence of movement, so far must there be a degree of separateness of representation of that movement by (*a*) distinct cells in the nervous centres. And yet, of course, the separation is not isolation; on the contrary, the greater the differentiation, the more complete the integration of the separate elements, for they have to act together or in succession.

Each of these varieties of fits beginning unilaterally depends, I believe, on discharge of the nervous arrangements of some particular series. The mode of onset gives us a clue to the series. Thus, those convulsions which begin in the hand are supposed to depend on a discharge beginning in parts of the cerebrum where the hand is largely represented in movements to which other movements (those of the arms, eyes, and leg) are sequent and

---

(*a*) I requote the following from an article I published *Brit. Med. Journ.* May 10th, 1873:—

"The significance of the fact, that the hand is the part in which convulsions, beginning unilaterally, most often start; that the arm suffers first, or most, or both, in the greater number of motor affections from brain disease (hemiplegia, chorea, paralysis agitans), will be better realised after reading Herbert Spencer's remarks on tactual organs, in chap. viii., vol. i., p. 359 of his "Psychology" (second edition), from which I give these extracts.

"He points out and shows the significance of the 'striking instances which the animal kingdom presents of unusual sagacity co-existing with unusual development of organs, which, by the help of complex muscular arrangements, give complex tactual impressions.' After remarking, that it will perhaps be difficult to understand why *touch*, the simplest and earliest sense, should in its higher forms be more than any other sense associated with the advance of intelligence, he says: 'The explanation lies in the fact that tactual impressions are those into which all other impressions have to be translated before their meanings can be known.' Of the human hand:—'All that we need here notice is, the extent to which, in the human race, a perfect tactual apparatus subserves the highest processes of the intellect. I do not mean merely that the tangible attributes of things have been rendered completely cognisable by the complex and versatile adjustments of the human hands, and that the accompanying manipulative powers have made possible those populous societies in which alone a wide intelligence can be evolved. I mean that the *most far-reaching cognitions, and inferences the most remote from perception*, have their roots in the definitely combined impressions which *the human hands* can conceive.' [No italics in original.]

"The study of cases of disease of the nervous system appears to me to supply continual illustrations of the correctness of many of Spencer's deductions."

In an article, *Lancet*, Feb. 15, 1873, also I referred to the above remark by Spencer, and pointed out that cases of hemiplegia and unilateral convulsion with lateral deviation of the eyes show us part of the physical process for the "translation" of visual ideas into tactual ones. I there also refer to the corresponding sensory symptoms, hemiopia and hemi-anæsthesia.

(*a*) It seems to me to accord with this that the highest centres (anterior and posterior lobes) have smallest cells. Hitzig and Ferrier's points of excitation, that is to say, the subordinate motor centres have many very large cells. I should, for theoretical reasons, expect that of the subordinate centres, those which represent movements in small muscles (eyes, face, and hands) will have cells comparatively small—smaller than the cells superintending movements of the large muscles of the limbs, but not so small as the cells of the very highest centres. As previously suggested it is probable that instability of numerous small cells will produce currents of greater "intensity" than instability of the same quantity of grey matter in few large cells; or it may be more correct to say that when small and large cells are subjected to the same abnormal nutrition the small cells sooner become unstable.

subordinate. It is probably a discharge of the motor element in the substrata of tactual ideas. Convulsions which begin in the side of the mouth or tongue probably depend on discharges of centres which are the substrata of words. Again, in fits beginning in the foot the internal part discharged contains nervous arrangements for certain movements of the foot and lower limb, to which certain other movements (those of the upper limb) are sequent and subordinate. In *this* series the foot has the leading representation. Hence the remark that the mode of onset is the most important matter in the paroxysm for our consideration. *It points to the part of the brain which discharges, or where the discharge begins.* The leading movements are developed first. As is thus implied, I do not believe that nervous centres represent limited regions of muscles, nor even isolated groups of movements. There are parts where, for example, the ocular, manual, and pedal movements have the *leading* representation. This statement implies the further belief that any part, especially such an one as the hand, is represented in innumerable places. Hence "compensation" (never absolute) in "destroying lesions." The seizure may be limited or universal; there are all degrees of range. But it is to be observed that when universal it becomes universal; the spasm is not at once contemporaneous; it is a sequence. It begins in a certain part in each patient, with rare exceptions, in the same part, and *spreads* over the body. Probably in no case of convulsions, even in those of "genuine" epilepsy, is the convulsion ever universal in the sense that the whole of the muscles of the two sides of the body are convulsed absolutely equally and quite contemporaneously. In those cases of epilepsy where the spasm is nearly universal and contemporaneous, there is some part which suffers somewhat sooner, as well as some part (one side) which suffers somewhat more. Indeed, it follows from the doctrines of Evolution that there may be all degrees of difference, from cases in which the spasm begins very locally, very deliberately, and spreads very gradually, to cases in which the discharge is sudden and nearly universal at once. In the former there is discharge of lower, in the latter of highest centres. (a)

The reader will note that there are two *kinds* of difference here spoken of—(1) that convulsions depending on discharge of lower centres will begin deliberately in parts and spread to other parts, whilst the convulsions from discharges of higher centres will be more nearly universal at once; (2) the discharge in the former will be slower than in the latter; it will be of less "intensity." In what follows we limit ourselves to the unilaterally beginning seizures.

A patient may have attacks of spasm limited to the hand, or even to one finger, or to the arm. A patient may have spasm of one side of the face only, or spasm of one foot or of one toe. It not unfrequently happens that the patient has limited fits before he has his first one becoming universal. Both the limited fits and those becoming universal begin in the same part. The patient who has been long subject to fits may have on one occasion a partial fit, and on another a universal seizure. Thus, suppose the fit to begin in the right index finger and thumb, there may be one day twitching almost limited to these digits, another day the arm may be in spasm, on another occasion the whole of the right side is seized, on another occasion the spasm may spread to the left side—the patient becomes universally convulsed. Hence, then, we have to speak not only of Ranges of the spasm, but of the order in which parts are involved in any range—Sequence of spasm. In observing a paroxysm we have to note both with care.

Let us take in illustration a case in which the spasm begins in the hand:—(*a*) We note the complete range of the convulsion; for example, we may have to say "the spasm involved the arm, face and leg of the right side: (*b*) we note the order in which it "went over" the parts of that range; as, for example, we may have to say, "it began in the hand, passed up the arm, attacked next the face, passed down the leg." We shall afterwards point out that this sequence is a compound sequence, although, for convenience, it is here spoken of as if it were simple.

(*To be continued.*)

ADDRESS IN SURGERY.

By W. F. Favell, M.R.C.S. Eng.,

Surgeon to the Infirmary, Sheffield.

(*Continued from page* 130.)

Again, perhaps, the most obvious cause of these diverse opinions lies in the fact that, in cases of depressed fracture, we can hardly lay down a hard and fast line of treatment—much must be left to the careful and anxious consideration of the surgeon unhappily meeting with such cases. I think recent experience has abundantly proved that compound depressed fractures of the skull in adults do get well without operative interference; and in illustration of this fact, I beg for a moment to refer you to three cases published in the *British Medical Journal* of July 8th by Mr. Gamgee, of Birmingham. Here we find rapid and uninterrupted recovery from compound depressed fracture of the skull in adults, one man being fifty-five years of age, and the other two twenty-five years old. They were all treated by perfect rest, cold to the head and aperients. I could adduce other instances, but I refer to these as cases recently published, and probably familiar to many readers of the journal.

On the other hand, it is a well-known fact that such happy terminations are by no means constant, and that the trephine or some similar instrument has sometimes to be used to relieve inflammatory symptoms, which occur as the result of irritation set up by the fractured bone, or to give exit to pus. Even then recovery is by no means to be despaired of, though, of course, operative interference under such circumstances is far less promising than when undertaken without the inflammatory complication. Referring to my notes of cases in the hospital, I find that only once in the last five years have I had recourse to the trephine, and I did so in what, I almost think, is a typical case for operation.

H. D., a woman, aged 39, was brought into the infirmary with a history that she was engaged in some street row, and was knocked down by a stone thrown into the crowd. I found a large wound leading down to a comminuted punctured fracture, the portions of bone being driven deeply down. There were no head symptoms. Finding it impossible to pick out the depressed portions with forceps, I removed a semicircular piece of the sound bone with the trephine, and was able then easily to remove six comminuted portions of bone, some of them driven under the uninjured bone, and amounting in the aggregate to a piece as large as a half-crown. The dura-mater was scratched, but not punctured. The woman was kept quiet, with cold to her head, and made a rapid recovery without any untoward symptoms. I think I may instance this as a case in which it is extremely doubtful whether so fortunate a result would have been obtained had I refrained from operation. I think, perhaps, there is a tendency in these days to overrate the danger of operative interference in such cases, for, where grave bone injury already exists, and where air has already had access to the dura mater, and probably also foreign bodies, such as grit and dirt, it is open to question whether an operation such as I have just described, performed with all possible care and delicacy of manipulation, adds very materially to the existing danger.

Certainly, I should be little disposed to lay down a defined line of treatment in cases such as I have been describing. Much must be left to the discretion and anxious thought of the surgeon, and whilst bearing in mind, on the one hand, that depressed compound fractures of the skull, even in adults, do get well without operation, one ought not to hesitate to interfere where the existing conditions of the fracture are such as to make one feel that there is probably less risk in interference than in simply waiting for results.

(a) We have, however, to bear in mind that certain regions of the nervous system are more liable to damage than others, and it is significant that, as a matter of fact, there are two large groups of cases with few intermediate cases.

But time warns me to leave this most interesting and important surgical question, and to pass on to the consideration of one or two others, with a few brief remarks; and whilst on the subject of bone injuries, I should like to say a few words upon, and illustrate by an instructive case and equally instructive preparation, cases of fractures of bone in the immediate vicinity of important joints. I think there are few cases in surgery in which the accurate diagnosis is often more difficult, the anxiety involved greater, and the results less satisfactory, than in cases of this nature. Every practical surgeon is familiar with the impaired utility of wrist and hand which we occasionally see, particularly in old people, as a consequence of the fracture of the carpal end of the radius; and, again, impaired mobility of the elbow-joint is not unfrequently seen as a result of fracture through some portion of that complicated and important articulation; and I venture to say that such consequences are sometimes unavoidable, in spite of the most carefully conducted treatment; nay, I think I may go even further, and assert that cases do occur in which the surgeon, by skilful and carefully conducted treatment, has obtained the best results he could hope for, and which still are failures in the eye of the patient, ignorant as he is of existing conditions and almost inevitable consequences.

Surely, gentlemen, these considerations should teach us a lesson; they should teach us to look very charitably upon alleged failures in treatment, or upon so-called cases of malpractice. It is one thing to criticise the treatment of a deformed or distorted joint weeks, or perhaps months, after the receipt of injury, when all *immediate* effects of such injury have disappeared, but it is a very different thing when contusion, inflammation, swelling, and pain obscure the injury and interfere with manipulation, so to direct our treatment as always to ensure a satisfactory result.

The case to which I wish to direct your attention for a few minutes, and which, through the kindness of my friend, Mr. Wheelhouse, I am enabled to illustrate by a very instructive preparation, is one of dislocation of the hip, complicated, as I believe, by fracture of the acetabulum—that is, of the rim of the acetabulum.

A. B., a young man, a commercial traveller, was standing on the platform at a railway station when he saw the train by which he wanted to travel passing rapidly through the station; he ran up to it, sprang upon the foot-board, and attempted to grasp the door of a carriage, but, being swung round by the momentum of the train, he was unable to keep his hold, and was thrown violently upon the rails, rolling over and over when he came to the ground. He lay stunned for a few minutes, and when he attempted to get up found his right leg so injured that he could not rise. He was carried into the waiting room, and was seen very shortly afterwards by Dr. M., the railway company's local medical officer. This gentleman made a very careful and deliberate examination of the injured limb, and, as manipulation gave great pain, he put the sufferer under the influence of chloroform, so as to give himself every opportunity of arriving at a correct estimate of the nature of the injury. After nearly an hour's examination he came to the conclusion that there was no dislocation, no fracture, but that the man was suffering from severe contusion. Afterwards the sufferer was carefully laid in a railway carriage and conveyed to his home in Manchester. Here he sent for his own surgeon; the same examination again was gone through, and the same result arrived at. As soon as the subsidence of swelling allowed it, a long splint was applied to keep the part perfectly at rest, and subsequently, as much pain about the hip was still complained of, his medical man, for his own satisfaction and that of his patient, called in a third surgeon, a man whose extended experience in cases of accident was undeniable. He found the limb lying flatly on the bed beside its fellow; careful measurements, conducted in the orthodox manner, proved that the injured limb was as long as, and at one time rather longer than, its fellow, and he coincided in the conclusions already formed, and in the propriety of the treatment adopted; and so the limb was kept at rest for some time longer. Here, then, we have three surgeons, separately and carefully examining this hip, and arriving at the same conclusions. But mark what followed in this singularly interesting case. When lapse of time and subsidence of pain warranted it, the splint was removed, and he was allowed to get up and attempt to move about. He did so, and attempted to bear some slight weight upon the injured leg, and *after* that he noticed, *for the first time*, that the injured leg was rather shorter than the sound one. This amount of shortening speedily increased to the extent of a couple of inches, with inversion of the foot, and, to cut a long story short, he consulted a fourth surgeon, who told him that his hip was dislocated, and eventually an action for damages ensued. In consequence of this, Mr. Wheelhouse, of Leeds, and I were asked to examine the case and give evidence upon it. When we saw it, several months after the accident, the evidences of dislocation were clear enough; there were the characteristic shortening, the inverted foot, and the round head of the bone clearly resting upon the dorsum of the ilium. One of two things, then, must have happened in this case. Either (as was alleged) dislocation of the hip had occurred at the time of the accident, and had been overlooked, or else dislocation had taken place subsequently as a result of some obscure injury to the joint. Against the first hypothesis were the testimony of three surgeons, who had all examined it carefully for dislocation or fracture, the fact of the absence of deformity, and the absence of shortening of the limb; whilst in favour of the latter hypothesis, in addition to what I have just stated, was the fact that no shortening took place till the man put weight upon the leg, and then it was immediately noticed. The only way in which one could reconcile the fact of undoubted *present* dislocation with a history so opposed to its existence for some time after the accident was on the hypothesis that, at the time of the accident, which was a very violent one, there was fracture of the rim of the acetabulum; that, so long as no weight was put upon the leg, the head of the femur remained *in situ*; but that, as soon as weight was borne upon the leg, the head of the bone escaped from the damaged acetabulum, and was soon drawn up upon the dorsum of the ilium. This theory was very ably argued by Mr. Wheelhouse, and surely it was a reasonable one—more reasonable than that a dislocation presenting such marked features as dislocation of the femur on the dorsum ilii, should have been overlooked, though carefully searched for, by so many surgeons of ability and experience, and though the probability of such an occurrence was denied, I am in a position, through the kindness of Mr. Wheelhouse, to show you a preparation taken from a case of accident admitted into the Leeds Infirmary, since the occurrence I have just related, which admirably illustrates the argument then urged. The case was admitted into the infirmary for injury to the hip and severe internal injuries. Dislocation was diagnosed, and reduction readily effected. The patient lay in bed some days, and then died from internal injuries. During the removal of the patient from the bed the hip, which had been in perfectly good position so long as the man was at rest, again became dislocated, and a *post-mortem* examination revealed the condition I now show you, viz., "fracture of the rim of the acetabulum."

Erichsen, speaking of the treatment of such cases, says:—"But with every care, a return of displacement will readily take place, and an unsatisfactory result can scarcely be avoided—shortening of the limb, and consequent lameness being almost inevitable." Cases such as this one I have just related are of immense practical interest both to the surgeon and his patient; and certainly the patient has a right to expect that everything shall be done for him that careful judgment and judicious management can effect; but how often does the surgeon get undeserved blame when he has the misfortune to treat an injury so complicated that, in spite of all care and skill, he cannot avert an unsatisfactory result. I can imagine and excuse a man being angry when he finds himself permanently crippled by an accident which at first, to all appearance, may not have seemed of a very formidable nature, but surely we, fellow-workers, all so fallible, ought to criticise the work of our brothers in a spirit of the widest charity.

The mention of Mr. Wheelhouse's name in connection with this case, in which I was associated with him, reminds me how this address was originally placed in his hands, and how generously and gracefully he relinquished it when the place of meeting was changed, and gives me the opportunity of paying a passing tribute to his surgical enterprise by a few remarks on what, as far as I know, is an important and ingenious novelty in surgery. Some months ago I had an opportunity of examining, in the Leeds Infirmary, a case then under treatment, in which Mr. Wheelhouse had cut down upon, resected, and united by ligature, the divided ends of a sciatic nerve, which had been accidentally cut across some months previously. The history of the case was briefly as follows:—

The patient, a man aged 22, nine months before admission, was climbing over a fence, when the railings gave way, and he fell backwards upon a scythe which he was carrying, The wound, which must have been an extensive one, as the cicatrix measured nine inches, was situated just below the left buttock. At the time of admission he was able to walk with difficulty, there being considerable dragging of the left leg, and as he lifted it the toes fell to the ground. He was unable to use the muscles of the back of the leg, and there was loss of sensation on the outer side of the leg and foot, the inner side retaining sensation. These conditions, taken in connection with the situation of the cicatrix, led to the inference that the great sciatic nerve had been divided, resulting in paralysis of parts supplied by that nerve below the seat of division. The operation consisted in making an incision six inches in length in the course of the sciatic nerve, when the divided extremities were found an inch and a half apart, the upper segment being bulbous, the lower one flattened, and somewhat incorporated with the cicatrix. The two extremities were then cut off, the divided ends brought together, and retained by sutures of carbolised catgut. This was facilitated by flexing the leg upon the thigh, in which position it was retained for some time. The man made a rapid recovery. When I saw him, two or three weeks after operation, cicatrisation was almost complete, though the leg was still retained in its flexed position; but there was ample evidence afforded of returning sensation on the outer side of the leg and foot. In this case the restoration of sensation and motion appears to have been very gradual, but Mr. Wheelhouse informs me that, since his discharge from the hospital the patient has gone on steadily improving, and gaining power in his former paralysed limb.

I have also the notes of a case of division of the median nerve by a wound from glass. It was treated in the same way ten weeks after the accident happened, but the result does not appear to have been so satisfactory, as, though some amount of return of sensation and motion followed the operation, as the wound healed and cicatrisation progressed the sensation gradually diminished and numbness increased.

Two other cases I have records of, in which the divided ends of the nerves were brought together by suture immediately after the accident. In one case the median nerve, in the other the ulnar nerve, were entirely divided. Both cases were boys of fourteen years of age. In one month from the occurrence of the accident both boys were discharged with their wounds healed, and sensation was perfect in each instance.

Now, I think I may instance these as four very suggestive cases. Perhaps they teach us no new facts in pathology, but, practically speaking, I think they are of importance. It will be observed that in the two cases in which some weeks elapsed between the receipt of injury and operation the results were, in one case very gradual and slow in their development, and in the other case satisfactory; but in the two cases in which operation immediately followed the accident, sensation, at all events, was rapidly re-established. Now, experience has amply proved that regeneration of nerve tissue, after nerve division readily takes place more or less perfectly under favourable conditions. Dr. Hassal says:—"The regeneration of the primitive nerve-tube admits of proof both by experiment and direct observation. The experimental proof consists in the simple division of nerves, or even in the removal of portions of them. The parts to which the nerve is distributed of course at first lose their sensory and motor endowments; these, however, after a variable time, are more or less perfectly recovered, thus completing the experimental proof. The recovery of the power of a nerve after the excision of a portion of it argues strongly the fact of the regeneration of the nerve-tubes, and this result by a careful microscopical examination, can be positively demonstrated. The number of tubes in the renewed part of the nerve is stated, however, to be less than in the original portions, and this in part explains the reason of the restoration of the functions of a divided nerve being usually but imperfect." Every surgeon, too, is familiar with the fact that parts which have been completely severed, such as tips of fingers, will, if reunited, regain sensation, though the nerves have been completely divided. Thus, under favourable conditions of position, we may look for such an amount of return of sensation and power of motion in parts supplied by divided nerves as shall not materially interfere with future usefulness; but the practical lesson to be learnt from such cases as these is that we may with safety so manipulate nerves as to insure such conditions of position. Perhaps the very painful, and sometimes even disastrous, result which has followed the ligature of an important nerve has deterred surgeons from interfering with them when divided. Sir A. Cooper records two cases of death from this cause—one from the ligature of the sciatic nerve to arrest hæmorrhage from an artery in its substance, and another in which the popliteal nerve was accidentally included in a ligature put round the artery. In both cases violent pains and death resulted.

In the cases I have recorded I find complaint of much pain after operation in one case—the first one operated on, in which the sciatic nerve is the one implicated. In this case there seems to have been great pain on the day of operation and the day following, but in the other three no mention is made of any disturbance caused by the operation. Probably the use of catgut sutures, we know, soon dissolves, and the fact that the sheath of the nerves was carefully selected as the portion to be principally included in the sutures, may have had much to do with such fortunate results.

As a beginning, then, I think these four cases are both interesting and encouraging. If in the case of a limb left paralysed by division of an important nerve, we can afterwards cut down upon, resect, and reunite such nerve, so as to restore power and sensibility to the parts supplied by it, at no great risk, much has been gained, and in cases of extensive laceration, involving important nerve trunks, these records raise the question whether it is not better not to be simply content with ligaturing bleeding vessels, and leave the nerve-trunk to the chance of assuming its original position, by carefully and accurately closing the wound, but to ensure the co-aptation of its divided ends by the careful introduction of catgut sutures.

I wish to say a few words upon Esmarch's elastic bandage and constricting band, for the case of cure of aneurism in the popliteal space, recently published by Dr. Reid, of the Naval Hospital at Plymouth, as effected by the application of Esmarch's method for restraining hæmorrhage, is well deserving of consideration.

Operating surgeons constantly come into contact with cases in which, either to themselves or their patients, the application of Esmarch's apparatus is a great advantage. In a town like Sheffield, where very heavy manufacture is going on, and where much machinery and steam power are employed, severe accidents, entailing great hæmorrhage, are very common, and repeatedly have we found the advantage of Esmarch's method in the amputation of mutilated limbs, where every drop of blood is of consequence. And, again, how much the work of the surgeon is facilitated in such operations as the removal of sequestra surrounded by new bone, and in the midst of soft structures, often unusually vascular from long-continued local activity. Here his view of parts is not obscured by the constant welling up of blood, and he is able to remove dead bone with the least possible damage to the new formation surrounding it, and acting as a substitute for it. In such operations, too, as those upon the foot, necessitating the disarticulation of small bones, with anatomical relations often obscured by disease and swelling its advantages are obvious.

Esmarch's method thus secures a twofold desideratum, in cases where its application is practicable, for it procures for the surgeon as clear a view of the parts he is operating upon as if he were operating on a dead body, and it secures for the patient the great boon of undergoing operation with the least possible loss of blood. I know it has been urged, in objection to its employment, that there is the risk of squeezing up into parts above inflammatory products, blood-clots, or partially disorganised blood, but I think with care in the application such accidents can rarely happen. Often as I have applied it, I never remember to have come across such results. The only unfortunate effects I have seen, I think, have been minor ones, such as some bruising and subsequent swelling of the stump, when probably the elastic ligature has been applied more energetically than was necessary. The method can hardly be called a new one, though I think to the ingenuity of Esmarch we are indebted for devising the means of making it so widely and generally practicable. But over and above these well known and generally acknowledged advantages, I must for a few minutes draw your attention to its employment for another purpose—the cure of aneurism. The subject of aneurism was so fully and exhaustively treated by Mr. Pemberton, of Birmingham, before this Association, four years ago, that little can be added to what he then advanced; but in the case recorded by Dr. Reid, when ordinary appliances failed, a rapid cure was effected by the application of Esmarch's bandage and ligature. The subject was a sailor, aged 37, with popliteal aneurism. Compression was first tried by genuflexion, which caused so much pain and œdema of the leg that it had soon to be discontinued. Afterwards, Carte's compressor was applied at the brim of the pelvis, and again in Scarpa's space; but after four hours continuous compression, severe pain again put a stop to treatment, and though pulsation in the tumour had ceased, it shortly returned, the opinion being that, although circulation through the femoral was controlled, a free supply of blood entered the sac through the collateral branches. It was then determined to try the effect of Esmarch's apparatus, not so as to empty the sac of blood, but keeping it filled, so to cut off all circulation through the limb as to allow of the coagulation of the contents of the sac. The limb was enveloped in the bandage from the toes upwards, but the bandage was passed very lightly over the knee, so as to exercise little pressure on the sac, and the thigh was then enveloped to the middle third. The elastic ligature was passed round the thigh, and kept on for fifty minutes, when pain above the seat of the constriction necessitated its removal. It was then found that all pulsation had ceased; the aneurismal tumour was hard, and, as a means of precaution, a tourniquet was applied at intervals over the femoral for a few hours longer, to moderate the current of blood through the artery. Pulsation never returned, however, and the man when seen some months afterwards was perfectly well. The striking feature in this case is the rapid cure. One can readily understand stagnant blood, in a vessel in a limb almost deprived temporarily of vitality, speedily coagulating; but it will be observed that this is not precisely the method of cure which we have been in the habit of considering the most desirable in aneurism. The efforts of surgeons, from John Hunter's time, has been so to retard the flow of blood as to encourage the deposition of laminæ of fibrine till a sac becomes filled. In his address in surgery at Birmingham, Mr. Pemberton says:—"What we want is a stream of blood flowing into the aneurism, that it should be more or less retarded there, and that there should be present something of the nature of a foreign body—for example, the fibrous laminæ—on which blood would coagulate and deposit its fibrine, for I strongly hold that what we want in these cases is a deposition of fibrine rather than a coagulation of blood. Surely the slow deposition, layer after layer, of solid fibrine in the sac, until filling in is complete, is a surer guarantee against future mishaps than if it were closed by a mass of suddenly coagulated blood." Now, whilst fully admitting the soundness of the views here expressed, I still consider this case well worthy of the attentive consideration of the surgeon. Certainly, I would prefer the gradual consolidation of the aneurismal sac by the deposition of fibrinous laminæ, but I am sure I have seen cases in which, either from the shape of the aneurismal swelling, or from the briskness of the collateral circulation, attempts to obtain consolidation by retarding the flow of blood have been useless; and, again, the pain induced by long-continued compression, or the nervous irritability of the sufferer causing him to be intensely sensitive to pain, may thwart our efforts to produce this gradual consolidation. Without presuming to draw conclusions from a single case, I still venture to bring this interesting one before the members of our association, affording, as it does, another and a novel illustration of the benefits conferred upon surgery by Esmarch. And if further experience prove that, in cases where we fail to obtain the gradual consolidation at which we have hitherto aimed, we can obtain rapid and lasting coagulation by actually stopping circulation in a limb, we shall have made another very important addition to the methods already in use for the cure of aneurism.

Gentlemen, I feel I have already trespassed long enough on your patience. I wish my crude and imperfect remarks had been more worthy of your consideration. I have been able to tell you little that is new, and nothing that is original. It is given only to the gifted few to originate ideas and introduce innovations. But still I may hope to have completed a far from useless task if I have succeeded in interesting this large representative gathering in even one or two important surgical questions, for it is only by the accumulation of facts, and by the interchange of experiences, that we can hope to throw light upon those delicate and difficult problems in which the profession we love so well abounds.

Wholly occupied, as many of us are, in the pressing practical work of our profession, too little time can frequently be devoted to the scientific and more attractive side of it; and yet the humblest worker in our great field of labour, diligently and conscientiously doing his daily work, may reap a rich reward, for, even before wealth and honour, welcome as they are, is the gratitude of our fellow-men for benefits conferred upon them, and the peace that comes from a life spent in trying to alleviate the sufferings of our fellow-creatures.

◆

REMARKS ON THE PRIORITY OF THE ANCIENT SYSTEMS OF MEDICINE.

By Thomas A. Wise, M.D., F.R.C.P., F.R.S. Edin.,
Late of the Medical Staff of the Bengal Army, Author of the "Ancient System of Hindu Medicine," &c.

Both sacred and profane history render it probable that when mankind emerged from their primitive home, they possessed great energy and organic activity, accompanied with a corresponding degree of intellectual force. This enabled them to select a fruitful country as their home, where they soon became rich and powerful, and at an early period assigned a particular class for the acquisition of knowledge. These individuals, distinguished for their power of observation and sound reasoning, opened a vast and interesting field for the exercise of their mental faculties, in the region of abstract speculation. Their knowledge and progress in civilisation was aided by their possessing the advantage of high rank in a regular and peaceable government, and a religion abounding in moral precepts.

The most ancient traditions and records of the Western nations refer to the "learning and wisdom of the East," without any distinct mention of the race or nation. Modern investigations tend to prove that the original seat of the Indo-Germanic, or Aryan family of man, was the high table-land contiguous to the lofty range of mountains extending eastward from the Caspian Sea.

Thence they descended to the fruitful plains in a southern and eastern direction, and at an early age another portion of the Aryan race commenced their wanderings towards the mysterious West. In both countries they distinguished themselves by their knowledge of the medical profession, and each prepared systems of medicine, the priority of which remains still an undecided question.

The age in which the ancient Hindu system was arranged cannot be directly stated; in consequence of their despising dates, as they considered life a transitory state of trial and suffering, and history of too little importance to occupy the attention of rational beings.

It is hoped that the following deductions will aid us in arriving at an approximate date when the two great works on Hindu medicine were composed, and enable us to compare them with the Greek system. The perishable material on which the ancient Hindu MSS. were written, rendered it necessary to have them frequently copied, in the course of ages, by scribes, often ignorant of the subject, and sometimes, perhaps, careless in their transcriptions. In ancient times the sources of error were to a certain extent avoided. The MSS. were regarded as of a sacred character, and only a limited few were permitted to copy them.

The sacred Hindu Vedas were more studied than the ancient Hindu medical shastres; as the latter were not considered sacred, greater liberties were taken with them, interpolations and clerical errors were introduced by illiterate transcribers. These causes render it very difficult to discover the age of the writings, except by comparing them with other Sanscrit works, the age of which is known. The ablest Sanscrit scholars allow that Charaka and Susruta, the two great commentators of the Ayur Veda, the supposed sacred revelation regarding medicine, are more recent than the grammarian Panini, (*a*) as neither work is mentioned by him, while both are noticed several times in the Mahábhárata. Professor Wilson supposed this great epic was written in the second century before Christ; and, like Panini, was added to, in the course of centuries. Hessler, in his work on Susruta, considered that it was written a thousand years before Christ. (*b*)

We have, at this early period, two systems of Hindu medicine, complete in all their parts, founded on anatomy, exhibiting an extensive knowledge of materia medica, and the practice of medicine, an expertness in the manipulations of pharmacy, and a bold and skilful knowledge and practice of surgery. We find the Hindu systems of medicine were originally written on the ancient form and construction of the Sanscrit language; so old, as to be considered the production of the deity, when there was no prejudice of caste, before Polytheism was introduced into the Hindu religion, and in the heroic age, previous to the Mahábhárata.

In considering the Greek system of medicine, we find their physicians and philosophers were indebted to the East for a portion of their knowledge. Pythagoras and Plato obtained many of their philosophical ideas from the Hindus, and the internal evidence of the Greek works proves that the Schools of Hippocrates derived a considerable share of their knowledge from the East. Galen mentions that Hippocrates was often at Smyrna in Asia Minor, (*c*) and Mercurialis believed that he travelled in Lybia in Africa, and Scythia in Asia. (*d*) Hippocrates may have visited this northern country to examine the enlightened and skilful Indo-Scythian people, whom Alexander the Great found so expert in the cure of diseases; and in these northern parts of Asia he may have consulted the Hindu sages, and studied their drugs and medical records. The learning he was in search of was there; and the following statements prove his acquaintance with their writings:—

1. The systematic works of the Hindus were most probably prepared from the third to the sixth century B.C.; and long before the age of Hippocrates, the original Ayur Veda existed, from which the other classical works were derived.

2. As medicinal plants have their properties developed in particular soils and climates, they indicate the nations among which they were first used for medicinal purposes, and explain the antiquity of the cultivation of medicine by certain races. The names and medicines recommended in the medical works of Hippocrates often indicate the schools of medicine from which they were borrowed. We find that Hippocrates used in his practice a number of Indian plants, imported from that country into Greece, for their well-known properties; such as *Sesamum Indicum*, Lin., *Hyperanthera morunga*, *Cardamomum*, *Amomum*, *Laurus cinnamomum*, *Valeriana Jatamonsi*, *Boswellia thurifera*, *Galbanum ammoniacum*, *Sagapenum assafœtida*, &c. (*e*) He also used black and long pepper, ginger, cassia, spikenard, *Calamus aromaticus*, &c., which are all the products of India or neighbouring countries.

3. The internal evidence of the works of the School of Hippocrates proves them to have been compilations, derived in part from nations further advanced than the Greeks in the knowledge of particular departments of the healing art. The ancient Hindu physicians considered dissection as a necessary part of the education of the medical practitioner. Their method was rude and imperfect, but many of their conclusions were correct, as we have proved by the result of their osteological enumeration, and the accuracy of their description of the internal organs, and of the large vessels of the body. (*a*)

The ancient Hindu surgeons performed the most difficult operations; such as the Cæsarean section, embryotomy, lithotomy, &c. The first description of the last-named operation was given by Susruta, and was afterwards made known by Celsus, (*b*) who derived his information from Egyptian surgeons, and they again acquired their knowledge from the East. Hippocrates, the judicious surgeon and benevolent practitioner, allowed, it is incorrectly stated, the performance of this operation only by uneducated quacks. (*c*)

From these facts it would appear that at an early age the Hindus had made very considerable progress in the healing art, which enabled them to prepare systematic works on medicine, based on their own practical knowledge of anatomy, to which, at that time, the prejudice of mankind in general was so much opposed. Susruta informs us that an accomplished physician must possess an acquaintance with books, or theoretical knowledge, with the dissection of the human body, or anatomy, and a familiarity with the appearance of disease, or practice of medicine, This knowledge explains how the ancient system of Hindu medicine was so complete in all its parts, and warrants the inference that several centuries were required to complete them. (*d*) While the nations of the West have been slowly advancing, and mutually aiding one another, during the last two thousand years, the Hindus, by the depressing influence of Brahmanical intolerance and internal warfare, are now in a lower social condition than they were three or four centuries before the Christian era.

PATHOLOGICAL ANATOMY OF THE BRAIN—LOCALISATION IN CEREBRAL DISEASE.

By Prof. Charcot.

Translated from the *Progrès Medical.*

CHAPTER IV.

Gentlemen,—I think enough has been said concerning the individual history of the various elements which enter into the composition of the grey substance. We must now examine the mode of arrangement of these elements, and what are the differences that can be produced, whether in this relation or in relation to the constitution of the elements themselves in each of the regions which show the fundamental fissures on the surface of the hemispheres. There is a mode of arrangement likely to be considered as representing the most common and most scattered type—it is the one where we distinguish in thin sections, under the microscope, five layers superposed. In the anterior lobes it is met with nearly everywhere. The elements are portioned out in the following manner:

1. The first layer, the nearest to the meninges, is almost exclusively formed by connective tissue. The nervous elements are here rarely met with; still, Kölliker and Arndt describe towards the surface, beneath the pia mater, a layer of nerve tubes, parallel and very delicate. There also the nerve cells are very disseminated (Fig. 5, 1). To the naked eye this layer has the aspect of a small white zone. The want of colour appears to arise from its poverty in nerve elements, and from the small number of capillary vessels it contains. In effect the small arteries which penetrate the cortical layer give numerous capillaries only to deeper parts.

(*a*) He died B.C. 593. See Goldstucker's learned history on "Panini's Place in Sanscrit Literature," p. 83 et seq. He lived before Sakea Muni, the founder of the Buddhist religion, who died about 543 B.C.

(*c*) This injunction in the oath that was taken before entering upon the practice of the medical profession among the Greeks, was most probably a Mahommedan interpolation.

(*d*) See Prof. Wilson, l.c.; and note on "Mill's Hist. of India," vol. ii., p. 232.

2. The second layer (Fig. 5, 2) is characterised by an agglomeration of pyramidal nerve cellules of the smaller species, very numerous, and massed together, and which communicate to it a very distinct grey colour.

3. The third layer (Fig. 5, 3) is in great part formed of pyramidal cellules, some of moderate dimensions, others voluminous. Some more scattered than others are situated in the most inferior part of this layer, and even penetrate into the next layer. Besides these cells we also find in this third layer fasciculi of medullary fibres which penetrate perpendicularly to the surface of the grey cortical substance and which form, in the interval between the groups of pyramidal cells, species of columns. It is in certain regions in the most inferior zone of this layer that the giant cells exist.

It would seem that the rarity of cellules and the presence of medullary fibres ought to give to this layer a white colouration, but such is not the case ; the truth is that, in reason, no doubt, of the presence of the pigment of the cellules, and of the number of capillary vessels, this region of the cortex of the convolutions presents to the eye a yellowish colour.

4. Next comes the fourth layer (Fig. 5, 4) where we perceive granules or globular cellules of an indefinite character, and the fifth, where we again find the fusiform cellules, of which we have just spoken (Fig. 5, 5).

These summary investigations may enable us to appreciate the interest presented by an examination of the structure of the grey cortical substance of the convolutions. Besides, we have long since learned that certain regions of the grey cortical substance differ in a very notable manner as regards the structure, concerning which the most complete and the most recent investigation is that carried out by M. Betz, the results of which were published in the *Centralblatt* of last year.

M. Betz's object is to study, convolution by convolution, the modifications of texture which the grey substance may present. With that point in view, it is necessary to distinguish, according to him, two fundamental regions at the surface of the hemispheres, which are very nearly limited by Rolando's fissure.

Anterior to this fissure, the grey cortical substance is characterised by the predominance of the pyramidal cells of large dimension over the globular cellules. The orbitar region is comprised in this district.

Posteriorly the region comprises all the sphenoidal lobe, the occipital and the median part as far as the anterior border of the quadrilateral lobe. There the granular layers predominate over the large cells, which are comparatively rare.

Besides, there is in each of these regions a special character which is worth referring to. Let us occupy ourselves in the first place with that of the posterior region.

1. The nervous elements, well developed, are here rather voluminous cells. According to M. Meynert, they were the largest which could be found in the cortex of the hemispheres before the discovery of the giant cells. They are sometimes 1-40th inch in diameter. But the protoplasmal prolongations are not very numerous ; the basal prolongation is directed horizontally, and sometimes is thus the means of communication between two cellules. The territory where we observe this disposition comprises (a) the cuneus, (b) the posterior half of the lingual and fusiform lobe, (c) all the occipital lobe, (d) the two first sphenoidal convolutions and the communicating fold. According to M. Betz, this region would be destined to the functions of sensibility. It is some time since, for anatomical reasons to which we shall return, the posterior parts of the brain have been designated as the seat of the sensorium.

2. The region of the anterior lobe which deserves special mention could be called—you will see why—the department of the gigantic pyramidal cells, or, better still, motor cells. It comprises the anterior frontal convolution in its entire extent, the superior extremity of the anterior parietal lobe, and lastly, a part which we will shortly study under the name of the paracentral lobe, and which is found at the internal aspect of the hemispheres, at the extremity of the ascending convolutions of those regions, frontal and parietal. It is there that the giant cells almost exclusively exist. Their apportionment is not uniform, for they are more numerous than elsewhere at the superior extremities of the two median convolutions, and especially in the paracentral lobe. They are disposed in groups or in islets. We find them at those points just indicated in apes of all species—in the inferior tribes as well as in the chimpanzee. Lastly, in the dog, M. Betz has observed these same cells in the parts designated by Fritsch and Hitzig as motor centres, *alias* the neighbouring parts of the sulcus cruciatus. What increases the interest of that fact is, that in the dog the giant pyramidal cells only existed in the regions called psycho-motor.

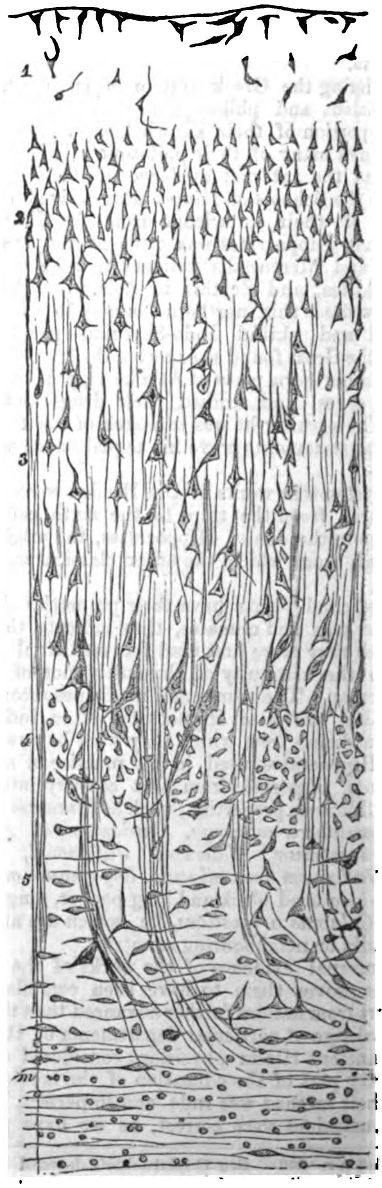

FIG. 5 (*taken from Meynert*). Nos. 1, 2, 3, 4, 5, represent the layers of the grey cortex. M, the medullary substance.

No doubt, gentlemen, it has not escaped you that in the ape this apportionment of the large nerve cells is very nearly the appanage of the convolutions where experiment has shown, in the hands of Dr. Ferrier, the existence of motor points—that is to say, the central convolutions. This is an interesting result furnished by histological study, and which, combined with experiments and anatomo-pathological facts, cannot fail to throw some light on cerebral localisation.

◆

ON MODES OF DEMONSTRATING THE ACTION OF THE MEMBRANA TYMPANI.

An interesting letter on this subject was published lately in *Nature* by Mr. John McKendrick. The movements of the bones of the tympanum in connection with sound-waves were first observed and their excursions measured by Buck ("Archiv. of Ophthalmology and Otology," vol. i., 1870), and more recently by Dr. Charles H. Burnett of Philadelphia, as recorded in the same journal for 1872. The method followed in these researches was to expose the bones and membrane by chiselling away a portion of the wall of the tympanum, sprinkling on the chain of ossicles a little powdered amylum, so as to secure bright vibrating points, throwing light into the cavity by means of a condenser, and observing with a microscope of low power the excursions of the vibrating points when sound was conducted into the external ear. Various interesting deductions were drawn from these experiments as regards the amplitude of the excursions of vibrating points on different portions of the conducting mechanism, and as to the effect of variations of the fluid pressure within the labyrinth on the extent of movement. In the last number of the same journal an interesting paper appears from Dr. Clarence J. Blake, of Boston, "On the Use of the Membrana Tympani as a Phonautograph and Logograph," accompanied by a plate. Dr. Blake's method consists of exposing the membrane and chain of bones, and fixing a light style (made "by splitting long wheat straw, scraping the inner cortical substance away, and separating single fibres") to the membrane. This style is caused to record its movements on a plate of smoked glass which is "carried smoothly and at a uniform speed in a direction at a right angle to the direction of the excursion of the style." . . . "The membrana tympani being set in vibration, and the carriage (bearing the smoked glass) drawn by its weight, moving at right angles to the excursions of the style, a wave-line, corresponding to the character and pitch of the musical tone sounded into the ear is traced on the smoked glass."

There is still a third method which Mr. McKendrick recently devised, chiefly for class illustration. It consists in converting the tympanic cavity into a manometric capsule, according to the method of Dr. Kœnig (*Philosophical Magazine*, 1873, vol. xlv. pp. 1—18, 105—114), and of viewing the oscillations caused by sound in a revolving mirror. A preparation is easily made from the ear of the cat. After sawing out the temporal bone, clearing away all loose tissue, and exposing the tympanic bulla, two small holes are made in the latter by means of a fine trephine. Into these holes two glass tubes, of corresponding diameter, are cemented with sealing-wax—the one for leading gas into the tympanic cavity, and the other out of it. The preparation (which may be preserved in a moist state in a well-stoppered jar for a long period, and be used over and over again) is firmly fixed in a vice, one tube is connected with the gas supply, and the other with one of Kœnig's small burners. By means of a third tube inserted into the external auditory meatus, sound-waves are conducted to the membrane of the drum, the mirror is rotated, and the usual pictures corresponding to the pitch and quality of the sound are seen with exquisite delicacy. He has found tones of medium pitch (ut 3 to sol 4) produce the most distinct effects, and the vowels, if uttered with sufficient intensity, produce pictures which are quite characteristic. By using a preparation in which the auditory apparatus on each side is present, it is easy to devise an arrangement for showing the effects of interference, in a manner similar to Kœnig's well-known apparatus for that purpose, constructed on the method of Wheatstone.

Clinical Records.

CASHEL UNION HOSPITAL.

Excision of Astragalus and great part of Tarsus.

(Under the care of Dr. Laffan.)

I. P., farm-labourer, aged 18 years, admitted 23rd April, '75, with pain and swelling in dorsum of left foot. From his previous history it appeared that he dated the commencement of the affection from a sprain, received the previous July, while jumping into the river. He walked home on that occasion with difficulty, but after a couple of days went about his business as before. From this to the 23rd April, he felt however the foot stiff every morning and was inconvenienced by walking on uneven ground. Three weeks before admission he first noticed it swelled. Matter being evidently present, the swelling was opened the day after admission, when the bones were found diseased, and a considerable quantity of pus was let out. After some months the patient's condition made it manifest that the diseased bone should be removed if life was to be preserved, and excision was resolved on. On 28th June, Esmarch's bandage was applied, and the patient put under ether by Dr. O'Brien, of Bansha. No regular line of incision was observed, but the sinuses were freely followed. The entire of the astragalus was removed, as were also portions of the oscalcis scaphoid and cuboid. The parts were slow in healing, and some anxiety was caused by the inflammatory swellings which appeared at the inner and back parts of the heel in November. These, however, soon disappeared. The boy has now a foot but little, if at all, deformed; he enjoys as much use of it as of the other foot. I had him apprenticed some time since to the workhouse shoemaker, as I thought it more prudent not to expose him to the risk which the more active pursuits of a farm-labourer would entail of a recurrence of the scrofulous affection in the healthy remainder of the tarsus. I may mention that there was a very slight congenital valgus. I may add also that the diseased parts were excised chiefly by the gouge, and that Esmarch's bandage was found of great value from the clear view it gave of the diseased parts.

NEW OPERATION FOR UNUNITED FRACTURES.

In a brief pamphlet of eight pages Dr. M. Hill, of Bootle, Liverpool, gives the details of a new operation which he has devised for attempting to secure osseous union in ununited fractures: It is an ingenious modification of Duffenbach's operation for the same purpose—viz., the introduction of ivory pegs into the fractured surfaces. The method proposed by Dr. Hill is to drill the bones and introduce the pegs through a small opening made with a tenotome knife, performing the operation as far as possible subcutaneously, and sealing up the aperture antiseptically at its conclusion, thus avoiding the conversion of a simple into a compound fracture.

The instruments required for the operation are—"an Archimedean drill-stock, a steel drill four or five inches long, and a few ivory stilettes of the same length and diameter (or slightly tapering) as the drill. The drill and stilettes are similarly graduated in half inches, and the ivories are, moreover, grooved like a director in order to slide along the drill."

"The *modus operandi* consists in entering the drill through a puncture made by a tenotome down to the bone; the depth of the soft parts is now read off by means of the graduations; then if it be desired to bore into the bone to the depth of an inch, the drilling is proceeded with until the steel has penetrated an inch further than the original reading. The ivory stilette is now filed *half way through* an inch from the point, and after being soaked in carbolic oil, is guided by its groove down alongside the drill to the brink of the perforation in the bone, from out of which the steel is next lifted, the ivory slipped into its place, hammered, and by a smart lateral movement broken off at the filed notch. The operation is completed by withdrawing the remainder of the stilette and sealing the puncture with a bit of lint and plaster. By carefully following the foregoing details it will be found that an inch peg is accurately placed in an inch hole, consequently there is no portion of it projecting into the flesh, and of this we may be certain by seeing before it is broken off, that the reading on the ivory at the surface of the skin tallies with the previous reading on the drill, both being graduated alike. A further object is secured by the peg being grooved; a channel is thereby provided for the escape of fluids in the event of osteomyelitis being set up, thereby avoiding the danger and suffering caused by the damming up in the bone of inflammatory fluids as would necessarily be the case were the peg solid."

This operation, as far as the manipulative details are concerned, was successfully carried into effect by Dr. Hill in the case of one of his patients, a gentleman, æt. 35, who sustained a fracture of the thigh at the junction of the middle and lower third, the result of a railway collision at Wigan on the 25th of December, 1874. Unfortunately, owing to some peculiarity of constitution, probably connected with the rheumatic dyscrasia, the operation failed to secure the desired union; this failure, however, could not in any sense be attributed to defect in the operation itself.

The case is one of great interest, illustrating as it does the difficulties which may sometimes be met with in practice in dealing with cases of fracture. With the exception of some attacks of acute rheumatism, the patient seemed to possess a good sound constitution; there was no history of excesses, syphilis, cancer, scurvy, or scrofula; he was well nourished, if anything, being inclined to *embonpoint*. Undoubtedly want of union was at the outset due to the disturbing influence of a severe hacking cough, induced by elongation of the uvula. This was remedied by removal of the pendulous uvula, and brushing out the throat with perchloride of iron. Every measure that was adopted failed to secure the desired union, though the records of treatment extend over the space of a year. In December last resection was performed. The difficulties attending this operation were so great, that Dr. Hill is more than ever confirmed in his desire to give a fuller trial to the operation he proposes, and it certainly seems deserving of fair and impartial consideration at the hands of the profession at large.

FROM the will of the late Mr. C. F. Beyer, of Manchester, the Royal Infirmary of that city receives a legacy of £2,000. Earlswood Asylum for Idiots and the Margate Convalescent Infirmary each receive £1,000 as legacies from the late Mrs. Taylor, of Margate and Bayswater. Legacies in accordance with the will of the late Mr. James Baird, of Cambusdoon, Glasgow, have been sent to the Glasgow Royal Infirmary, £2,500; Western Infirmary, £2,250; Eye Infirmary, £250; Ophthalmic Institution, £100; Maternity or Lying-in Hospital, £100; Lock Hospital, £100; Benevolent Society for Relief of Destitute Sick, &c., £100; Convalescent Home, £300; Royal Infirmary Dorcas Society, £100; Samaritan Society, £100; Association for Relief of Incurables, £500; Training Home for Nurses, £100; Association for Providing Trained Nurses, £100; Medical Mission Society, £100; West of Scotland Convalescent Seaside Homes, £100; Ayr Hospital, £300; Kilmarnock Infirmary, £300; Destitute Sick Society, £50.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 23, 1876.

DR. GULLY.

THE characters and previous history of the persons involved in the recent investigation respecting the death of Mr. Bravo have been sifted, and subject to criticism by the public journals, without any hesitation or scruple; and, recognising the rights of the press to deal with the credibility of witnesses in such an inquiry, we offer no apology for referring to the relation of Dr. Gully to the case, and to our profession, and considering to what extent his antecedents as a medical man affect his right to be believed as a witness, or bear upon the question of his possible connection with such a crime. We are anxious not to be considered for a moment as suggesting that any charge of complicity in Mr. Bravo's murder has been established against him, for if even the strongest suspicions existed to that end, we look upon the case as still *sub judice*, and should not permit ourselves to strengthen those suspicions; and, moreover, we have not found in the examination of Dr. Gully himself, or any of the witnesses, the proof of any incriminating circumstance.

Thus much being said in justice to Dr. Gully, it is necessary for us, in justice to the medical profession, to disown in the most distinct manner any sympathy with, or relation to, that gentleman; and we make the repudiation with the greater force and emphasis because we regret to think that the general public and the press have scarcely done justice to our profession by distinctly separating Dr. Gully and his practices from us and our method of treatment. Dr. Gully, albeit he holds legitimate medical qualifications, and once engaged himself in the scientific practice of medicine, underwent long since a perversion, and ceased to be a recognisable member of our body. It is for the public to judge whether his subsequent career as a water doctor, a homœopath, a spiritualist, a mesmerist, and his final *rôle* as the paramour of a patient, indicate his conversion from scientific medicine to charlatanism as a sincere awakening to scientific light, or whether it bore rather the appearance of a deliberate abandonment of himself to the lucrative temptations of irregular practice. Of the nature of that practice the public know nearly as much as we do ourselves, but that the combination of spiritualism, infinitesimalism, and mesmerism occupy a close relation to swindling, and worse, has been abundantly proved by the doings of Dr. Gully's particular friend and fellow-worker, Home. With hydropathy pursued conscientiously as a method of treating disease, medical men are, to a certain extent, in accord; and even mesmerism may be tolerated, up to a certain point, as a dangerous but possibly an earnest delusion; but for the application of these methods of practice to infatuated old maids, amative widows, or weak-minded valetudinarians, with the end of wholesale deception of them, and depletion of their purses, the medical profession has nothing but abhorrence and disgust, and it cannot be silent in being, even in the vaguest way, mixed up with such transactions.

Dr. Gully many years since—elected to withdraw from the association with the medical profession, and we recall the attention of the public to that circumstance. He is not, has not recently been, and can never again be of us, or with us. We cannot unfrock him as Dr. Kenealy and Mr. Edwin James were, drummed out by their indignant profession, but we repudiate him and his practices, and regard no injustice to our fair fame greater than any doubt in the public mind respecting his relation to medical men and the science of physic.

◆

VACCINATION PROSECUTIONS.

The long and able letter which the Right. Hon. G. Sclater-Booth, President of the Local Government Board, has addressed to Mr. Serjeant Simon, M.P., on the subject of vaccination prosecutions, is well worthy attention, and it is only want of space that has prevented us from inserting it *in extenso* in our columns.

Mr. Sclater-Booth begins by stating that he has given his unwearied attention to the subject ever since the Vaccination Act of 1871 came into operation, and that he has most carefully considered the recent representations that have been made to him with a view of obtaining the appointment of a Royal Commission to inquire into the effects of compulsory vaccination. He next reminds Mr. Simon that just such an inquiry as is now asked for by a few unreasonable agitators, was made more than five years ago by a Select Committee of the House of Commons, which, says Mr. Booth, devoted a large portion of its time to receiving the evidence and representations of those opposed to the practice of vaccination. The leaders of what was called the "anti-vaccination movement" appeared before that Committee, and had—as no one who reads their report can doubt—ample opportunity afforded to them of establishing their case. This, in the opinion of the Committee, they failed to do on every point. It is evident, before the Government could be called upon to reopen a question thus recently and carefully decided, it would need to be satisfied that some new facts bearing thereon had come to light, and that material evidence of a kind and force calculated, if not to overthrow, at least to cast serious doubt on the conclusions previously arrived at, was likely to be forthcoming. But so far from this being the case, Mr. Sclater-Booth found, on comparing the evidence in the Select Committee's report with the statements which were made to him by the deputation, that all the facts and arguments on which the latter appeared to rely were substantially before the Committee. The writer thus passes on to the consideration of the working of the Act of 1871, from which it appears that as much as 95 per cent. of each year's registered births are finally accounted for on the vaccination registers, while the small percentage remaining is satisfactorily disposed of on other grounds than that of the objection of parents. From this important fact Mr. Sclater-Booth justly infers that "such results would have been wholly unattainable had there been any such general feeling of opposition on the part of the people to the Vaccination Acts as the deputation suggested." On the contrary, it further appears that in the great majority of the English districts in which legal proceedings were required, it has been owing chiefly to indolence and indifference of parents, and only in a small proportion on account of the objection to the operation, and still more rarely on account of their refusal to comply wtih the law. Moreover, in the year 1874, in which upwards of 700,000 children were successfully vaccinated, only 749 summonses were issued, and in a very large proportion of these the proceedings were little more than nominal. The general accuracy, however, of the Parliamentary returns has been called in question, and therefore Mr. Sclater-Booth, although by no means sharing in this doubt himself, intends to have a return for the years 1875 and 1876, which shall bring out the facts for those years in a still more precise form than has been hitherto adopted. With regard to the prosecutions themselves, this gentleman admits their tendency in some cases to create sympathy with the persons who were the subjects of them; but then again the persons proceeded against exercise an injurious influence on the administration of the law. in their respective localities, especially as they are often either well able to pay the penalty themselves, or are members of a society which pays the fine for them.

With regard to the propriety of continuing prosecutions, Mr. Sclater-Booth says that much must depend upon the special knowledge which the local authorities have of the facts of each case; and it will, he remarks, always be his policy to advise local authorities, after proceedings have been carried to a certain point, carefully to consider each case before further action is resolved on; and even when the latter alternative has been adopted, the decision to make or withhold the order for vaccination is entirely within the discretion of the magistrates.

Such are the chief points in Mr. Sclater-Booth's long and interesting letter, and on which we will now offer a few brief remarks.

It is evident from the last part of this letter, that Mr. Sclater-Booth doubts the propriety of carrying these prosecutions too far, and we think that he has every reason for doing so. As we said on a former occasion, petty prosecutions often defeat the very object they aim at, and often form the agitation which it is desirable to suppress. "This is the more likely to be the case," we remarked, "when peculiar views are held and acted upon by only a very small minority, and when the practical adoption of such views would trespass upon the welfare of the majority." At present the penalties inflicted upon these obstreperous opponents of vaccination, and who form but an infinitesimal portion of the community, are treated with contempt. Fine after fine is imposed, and fine after fine is paid by a Society which openly encourages its members to break the law. But what is to be done? "If," says Mr. Sclater-Booth, "any suggestion for limiting the extent to which proceedings may be carried in individual cases can be made which would not have, at the same time, the effect of weakening the obligations imposed on parents by the law, such suggestion shall have my attentive consideration. But in face of the evidence which is before me of the remarkable effect which this law has already had in the prevention of the small-pox mortality of young children (among whom alone can its results at present be manifested), my first duty is to see that its efficiency is maintained.

We do not, however, see that any suggestion worth following can be made, or that anything can be done short of either giving up all further proceedings after the first or second prosecution, or so modifying some of the clauses of the present Act as to render it even more efficient and uncompromising than it is now. Whether the principle of compulsory vaccination is wrong, as Mr. Gladstone, Mr. Bright, and one or two other eminent men have affirmed, we will not stop to inquire. It is quite evident from the Reports above mentioned, that the Vaccination Act of 1871 is, in respect of its main object, a great success—that the effect which it has already had in the prevention of small-pox, especially among children, is most remarkable, and that, moreover, it has not met with any opposition on the part of the public generally. Now the principle of compulsory vaccination cannot be far wrong where the practice is so very right; and the above facts amply justify the policy of making this operation compulsory throughout the United Kingdom. But still it is open to consideration whether the Vaccination Acts might not be so modified as to give, in exceptional cases, a little more liberty to the subject, and yet avoid the objections that have been urged against a repetition of these petty prosecutions, while at the same time some provision was made against any unfair advantage being taken of any concession on the part of the Government. It is quite evident that the power of proceeding in the first instance against, and of inflicting a fine upon, those who do not comply with the law, cannot be dispensed with, as such power enables the Government to have under its control those delinquents who have not neglected to comply with the Act from any personal objection they have to vaccination, but from sheer carelessness, indifference, or procrastination. Nay, more, the consideration of the subject may be brought within a still narrower compass, for in contemplating any modification of the Vaccination Acts, we must recollect that we have not to deal with the public at large, who are perfectly satisfied, both with the principle and the working of the Acts, but with a very small number of foolish and misguided men, who have clubbed together and dignified themselves with the name of a "Society," and who are doing all they can to force their opinion upon others, and to openly encourage a wilful disregard of these Acts. The whole question, therefore, resolves itself into the propriety or not of prosecuting for the second time those few individuals who are determined, in spite of repeated fines, to evade the law. To forego the power of taking any further proceedings, present or prospective, against these refractory opponents of vaccination, and the Society which represents them, would be simply playing into their hands, and would be an admission on the part of the Government of its own weakness, and of its inability or want of courage to act up to its own convictions. But it appears to us that under these circumstances one of two courses might be adopted. We might either make the penalties incurred by second and third convictions very heavy, and such as might, after the first conviction, take no further proceedings—but, with the provision that the Society would find it difficult or altogether impossible to pay, or we might provision that they would be liable to a still heavier penalty in the event of the unvaccinated child having small-pox, and even to be indicted for manslaughter in the event of the child dying from the disease. Such a course is both reasonable and practicable, and is the very same as that now sanctioned by the law, and adopted, in the case of those parents who have allowed their children to die of some malady rather than call in medical aid. Only a few days ago a member of that religious sect known as the Peculiar People was indicted for and found guilty of manslaughter for allowing his child to die from an attack of scarlet-fever rather than resort to the advice of a medical man. But the sayings and doings of the anti-vaccination league show that the above sect are not the only "peculiar people" in the world; and we do not see why, as respects the penalty imposed upon them for their open defiance of the law, the same punishment might not be inflicted in one case as in the other, more especially as the parent who obstinately resists the Vaccination Acts not only jeopardises the life of his own child, but that of other people's children also.

At all events, it is to be hoped that every thing will be done to maintain the efficiency of the Vaccination Acts, even as they now stand, and that the opponents of vaccination will find, as the Keighley Board of Guardians have lately found, that it is of no use for them to put their narrow views and prejudices against the written law, particularly when that law is for the good of the whole community, meets with all but universal approval, and is enforced with more beneficial results than the most sanguine sanitarian could have expected.

◆

Notes on Current Topics.

Failure of the Army Medical Short Service System.

In the House of Commons on Friday Mr. Dunbar asked the Secretary of State for War what is the number of vacancies in the Army Medical Department; how many appointments were announced as open for competition at the competitive examination to be held this month; whether time for entering candidates' names has not now expired; and how many candidates have entered their names?

In reply to the question of the hon. gentleman, Mr. Gathorne Hardy stated that there are seventy-seven vacancies in the Army Medical Departments, and fifty appointments were announced as open for competition at the examination this month. The time for entering candidates' names has now expired, and the number of candidates who have entered their names for competition is only forty-four.

This statement was received with cries of "Oh! oh!" and derisive cheers, and Mr. Hardy must have felt his position rather undignified and uncomfortable. It is evident that his short service scheme and £1,000 bribe is not more attractive to students than the many shifts of his predecessors. Why cannot Government see the expediency of dealing with its medical officers as any prudent commercial man treats his *employés*, and as the Crown treats its civil servants. If a bank desires the services of a good staff of servants, it does not offer them a temporary berth and a turn out with a bonus when they have learned their business; but, on the contrary, it holds out to them a permanent provision at a fair salary, and the permanence is almost as great an inducement as the salary. If the Government *did* succeed in attracting competitors, it would only get roving adventurers whose services would not be of great value to the country.

Cost of Pauperism in Ireland for the Past Year.

The total cost of poor-relief in Ireland, excluding medical charities and sanitary expenditure, for the past year was £771,551, against £817,218 last year, or a decrease of nearly £46,000 in the total amount spent. It is shown by the recent report of the Irish Local Government Board, that there has been a decrease of £41,772 in "in-maintenance and clothing," £11 in cost of "deaf and dumb and blind," £1,094 in "salaries and rations of officers," and of £4,040 in "all other expenses," but an increase of £1,189 in "out-door relief."

The following is a statement of the Parliamentary Grant for Medical and Educational purposes, and of its distribution for the year ended 25th March, 1875:—

	Amount claimed and granted for the year.		
	£	s.	d.
Medical purposes ...	69,962	10	8
Educational purposes	8,745	19	4
Total ...	78,708	10	0

The total amount claimed and allowed under the Parliamentary grant for the year ended March, 1875, namely, £78,708 10s., is £2,396 5s. 5d. in excess of the claim for the previous year, and arises chiefly from increases of salary.

Hence it will be seen that the total expenditure of poor-rates for all purposes, viz., relief, medical relief, burial grounds, registration of births, deaths, and marriages, sanitary measures, and expenses under Superannuation Acts was in 1874, £1,001,989, making a poundage of 1s. 6d. on the valuation. In 1875 the expenditure for all purposes was £975,044, or 1s. 5¼d. in the pound, showing a decrease of £26,945, notwithstanding that the sanitary expenditure was £25,016 more than in 1874.

Adulteration of Butter.

We have more than once directed the attention of our readers to the wholesale manner in which butter is often adulterated, and to the various means adopted to imitate the pure article. To detect, however, the exact nature of some of the impurities made use of is by no means an easy matter, while the conflicting evidence of analytical experts often defeats the ends of justice, and encourages the vendors of this important article of consumption to pursue their unprincipled practices. It would certainly be a step in the right direction if some of our chief analytical chemists held a conference and appointed a committee to find out the nature of the substances generally used for the adulteration of butter, and the method of analysis by which their presence may be most certainly detected.

The above remarks are suggested by a case which was recently tried in the Sheriff's Court, Glasgow, in which a provision dealer was charged with having sold a pound of adulterated butter. The assistant sanitary inspector deposed that the butter in question had been analysed by Dr. Clark, one of the city analysts, who found that it was adulterated with extraneous fat to the extent of two-thirds of its weight. Dr. Clark himself stated that he made his analysis by Bell's and Muter's modes of testing butter, which he believed were correct modes. Dr. Stevenson Macadam, of Edinburgh, deposed that he had made an analysis of the butter both by Muter's mode and by the old system of testing. By Muter's mode the butter appeared to be adulterated, and according to the old system it was quite sound. He believed the old system was the correct one, and the butter quite good. Dr. Dittmar, Professor of Chemistry in the Andersonian University, gave similar evidence as to the results of the two methods of analysis. He did not think Muter's was the correct way, and was of opinion that the butter was quite sound. Eventually some of the butter was remitted to Somerset House for further investigation. An answer has been received from the London analysts, who report that from the examination of the facts they were of opinion that the sample was made up almost exclusively of a fat which was not that of butter, and which had apparently been worked up with a little milk.

The Enforcement of Vaccination Law in Ireland.

Referring to the fact that the late epidemic of small-pox in Connaught had caused an increase of over 18,000 cases of vaccination in that province within the past year, the Irish Local Government Board says that however satisfactory it is to know that a certain number of persons have been themselves protected by vaccination from the disease of small-pox, and, so far from being a means of conveying the disease to other persons, it is not to such exceptional and spasmodic efforts that the public should be indebted for protection.

The complete vaccination of the population should be secured by sustained and continuous attention on the part of the registrars of births, medical officers of dispensary districts, and the several committees of management, and by Boards of Guardians, who are responsible for directing proceedings to enforce the provisions of the Vaccination Acts, and lastly, and mainly, by a firm administration of the law by the magistracy, who are apt to show excessive leniency in dealing with these particular cases.

A provision is made by the 58th section of the Public Health Act, Ireland, 1874, to enable any Justice of the Peace to make an order for the vaccination of any child under the age of fourteen who has not been successfully vaccinated, nor has had the small-pox, upon information of the facts being given to him by any registrar, or officer appointed by the Guardians to enforce the provisions of the Vaccination Acts; but it does not appear that this power has been exercised hitherto, or, at all events, not to any extent.

The Royal College of Science, Dublin, and the London University Examinations.

The students of this College, who were candidates at the recent first B.Sc. examination of the London University, passed in the first division, and one of these students, Ernest H. Cook, has obtained an exhibition of the value of £40 a year, tenable for two years. This exhibition is awarded to the candidate who comes out at the head of the first class in honours in chemistry. The competitors were very numerous, almost every institution in the kingdom sending up one or more. As this is the second time during the last three years that this exhibition has been won by students of this College, it shows that the chemical education given therein compares most favourably with that given in any of the colleges in the United Kingdom. We may also notice that at the recent examination of the Whitworth scholars, Thomas L. Daltry, student of the Royal College of Science and a Whitworth scholar, obtained one of the prizes for superior answering and for practical work.

Sanitary Inspection of Hotels and Lodging-Houses.

Amongst the many excellent ideas which obtained to practical application at the Social Science Congress last year, was one recommending the Council of the Association to suggest to the local sanitary authorities of watering-places the desirability of establishing a system by means of which owners of lodging-houses and hotels should be enabled to have their premises inspected and certified if found in a general healthy condition with reference to drainage and other sanitary arrangements. The Council solicited the views of the local authorities on the subject, and received a number of answers in reply, which have been considered, and on which is founded the following report :—"(*a*) That it is desirable that the system, in the first instance, should be a voluntary one, and that owners of lodging-houses and hotels should be invited by the sanitary authority of each town to apply to the medical officers of health to certify that the drainage and other sanitary arrangements of their respective houses or hotels are satisfactory, and generally that the same are in a healthy, habitable condition. (*b*) That these certificates be renewed every three months, or more often if the sanitary authority think it desirable, but that it shall be the duty of the medical officer of health between the renewals of his certificate, to visit the premises so certified as occasion may require, in order to ascertain that the same remain in the sanitary condition to which the certificate applies. (*c*) That a minimum charge, at the discretion of the sanitary authority, shall be made for the issue of such certificates. (*d*) That a register shall be kept at the town hall, or other public office, of the certified houses and hotels open to inspection without charge during usual office hours; and that local authorities should exercise their best efforts, by advertisement and otherwise, to inform the public of the regulations herein suggested. (*e*) That the owners of certified hotels and lodging-houses should be required to produce the certificate when called upon, and should exhibit the same in some conspicuous part of the house, and that this should be a condition of registration." This report has been forwarded to the local authorities of the several watering-places and health resorts in England and Wales for their consideration, and where practical, its adoption. Of course it will meet with opposition, all sanitary suggestions are certain of this, but we hope that the common-sense party will have a majority in most watering-places, and then there can be no doubt as to the result.

Dispensary Medical Relief in Ireland.

The tables published of the Irish Local Government Board in their recent report show the following difference in the years 1873-4 and 1874-5 in the four provinces:—

In Ulster there has been an increase of 1,479 cases at the dispensaries, and an increase of 7,699 of those attended at the patients' houses.

In Munster there has been a decrease of 2,565 cases at the Dispensaries, and an increase of domiciliary cases of 967.

And in Connaught there has been a decrease of 3,005 cases at the Dispensaries, and an increase in the number of cases attended at the patients' homes of 983.

The tables show for the totals of all Ireland a decrease for 1874-5 of 5,497 dispensary cases, and an increase of 12,524 of the more serious cases attended at the homes of the patients, giving a total increase, including both classes of cases of patients, of 7,027 cases for 1874-5, compared with the previous year.

Hypodermic Injections of Cold Water.

Some time ago M. Lélut sent a communication to *L'Union Medicale* on the relief of pain by hypodermic injections of cold water. Lately Dr. Dessau, of New York, has been giving a trial to this simple remedy to seven cases that came under his care. They were nearly all cases of articular rheumatism. In all, the pain appeared to be almost instantaneously relieved by the injection, and in several instances it did not return. Dr. Dessau, thinking that the relief obtained may have arisen from the mere puncture of the skin, as in acupuncture, inserted the needle in the manner adopted in that operation, but the effect was nothing to be compared with that experienced after the injection of cold water. In one case Dr. Dessau injected as much as ten syringefuls of water at one visit, so that there is no danger from the quantity employed; and he thinks this will be found a valuable and ready means of relieving pain, especially when it is not desirable to resort to the use of morphia and other narcotics.

It is very probable that this plan of treatment will often be found efficacious in the relief of that pain which is so characteristic of neuralgia and various forms of rheumatism. And we base this presumption not so much upon the result of Dr. Dessau's experiments, which are not sufficiently numerous to enable us to form a correct opinion, but upon the *a priori* consideration that the sudden applications of intense cold, such as that afforded by snow, ice, and freezing mixtures, has often given speedy and permanent relief in cases of neuralgia that have resisted all ordinary kinds of treatment.

Statistics of Lunacy.

From the 30th Report of the Commissioners in Lunacy, it appears that the total number of lunatics of all denominations in England and Wales, recorded up to last January was 64,916, being an increase of 1,123 upon the previous year. It must not, however, be supposed that this shows any considerable increase of insanity amongst us, as in the above calculation the annual increase in the population of England and Wales has not been taken into account.

Surrender and Imprisonment of the Keighley Guardians.

The members of the Keighley Board of Guardians (says the *Standard*) have at last found that law is stronger than opinion, and they are now all lodged within the confines of York Castle, there to remain until the 2nd of November next, when they will be brought before the Queen's Bench Division of the High Court of Justice to answer "certain trespasses and contempts." It will be recollected that on Friday last the anti-vaccinators of Keighley proved stronger than the officers of the high sheriff of Yorkshire, who held warrants empowering them to "attach" and convey to York Castle the six unarrested guardians, the omnibus containing the captives being dragged from the representatives of the law at the railway station, and the guardians being set at liberty. A truce was entered into, the chief condition of which was that the guardians should surrender themselves to the sheriff's officers at Leeds at eleven o'clock on Saturday morning, and this engagement was honourably kept. On Saturday morning the half-dozen "outlaws" met at the Keighley Railway Station, whence they proceeded by the Midland train for Leeds at 9.11. The names of the six guardians, who were loudly cheered as they left the station, are Messrs. R. A. Milner (chairman), J. B. Sedgwick, David Normington, Titus Ogden, Hezekiah Tempest, and James Newbold. At Shipley the sheriff's officers, who had arrived over night in Bradford, joined the train in which the "attached" guardians were travelling, and friendly greetings between the captives and their captors were exchanged during the journey. Arrived at Leeds the guardians were allowed to see their friends and take leave at the Queen's Hotel, and amongst those who were there to express sympathy were Alderman Tatham, Councillor Kenworthy, of the Leeds town council, and a large company of local anti-vaccinators. Shortly before eleven o'clock the guardians and the officers and their charge took seats in a couple of first class compartments, and after ten minutes had been occupied by cheering, shaking of hands, and good-humoured bandying of satire upon the anti-vaccinators or upon the framers of the vaccination laws, the train left the station. No attempt was made to rescue the "martyrs," and good order was maintained at the Midland and North-Eastern Stations by a strong detachment of the Leeds police force, under the superintendence of Mr. Henderson, the chief constable, and by a contingent of railway police.

We need not make any comments on the above deplorable events, as the whole scene just described speaks for itself. In another part of this journal, however, will be found our views on the subject, in connection with the very interesting letter which Mr. Sclater-Booth has recently addressed to Mr. Simon on the question of vaccination prosecutions. Oh, that the ghost of Jenner could arise, to cry shame upon such disgraceful scenes. It is just such occurrences as these which justify the suggestions we have made, and make it worth while considering whether the vaccination laws might not be made as effectual as they now are in carrying out the object for which they were framed, without irritating the prejudices and susceptibilities of men like the Keighley Board of Guardians and their sympathisers.

Vaccination in Ireland.

It is shown by the report of the Irish Local Government Board just issued that there is a decrease in the total number of cases vaccinated and revaccinated in all Ireland of 2,247 cases.

There was a decrease in cases "under one year" of age in each of the four provinces; but there was an increase in Connaught both in cases "above one year old," and "other persons." This increase was attributable to an outbreak of small-pox in that province.

The impulse given to vaccination in this year in Connaught was owing to the terror occasioned by the cases of small-pox which occurred, and the opportunity thereby afforded to the medical officers to extend the practice, the people of all classes willingly submitting to the operation under the influence of the temporary apprehension of contagion and death.

Similar results followed the widespread occurrence of small-pox in other districts heretofore; notably so in the province of Ulster in 1874, when 57,861 cases of vaccination took place in that province alone out of the 139,587 cases in all Ireland in that year.

Suffocation in Sewers.

It is very strange, and indeed a great shame, that something is not done to prevent the fatal accidents to which those poor labourers are liable who are employed to clean out sewers. Not long ago an inquest was held at Sheerness on the death of a man who had been employed by the government authorities to clean out a manhole to a sewer. The deceased was the first of the two or three men employed to go down, descending by means of a ladder. After he had been in the manhole for two minutes he was observed to sit down. A man named Meeney was sent to his assistance, but soon became insensible, and fell upon deceased. A third man partially descended, and managed to get Meeney up by means of a hook. The foreman then followed, but he also fell down insensible, and it was half an hour before the deceased could be got out. He soon afterwards died, apparently in consequence of having inhaled sulphuretted hydrogen gas. Shortly after this occurrence some men were sent by the Lambeth parochial authorities to clean out a main sewer which had been made the receptacle of the refuse arising from some ammoniacal gas works situated close by. The gang of men sent found the task so dangerous, on account of the poisonous emanations that they refused the work. One would think that such a representation would have opened the eyes of the parochial authorities to the necessity of taking some measures to protect the lives of their workmen. But no, another gang of men were sent, who also refused to enter the sewer. At last some men were obtained, who attempted to clear away the obstruction, and the result of this attempt was that two of the men were suffocated in the sewer, while two others suffered much from the effects of the poison. Of course, after the accident an inspector from the Board of Trade visited the factory and sewer.

In all cases where, as in the instance mentioned above, the sewer has not been cleaned out for some years, and especially when the labourers employed seem afraid to undertake the work, some means should be taken to ascertain the condition of the manhole or sewer, or such precautions taken with respect to the first man who goes down, as to render loss of life impossible. The nature of the deleterious gases pent up in these places, and the extent to which the air is impregnated with them, might be ascertained by means of a lighted candle, or by some chemical test, or, the Society for the Prevention of Cruelty to Animals might, unless they thought the life of a working man was not worth such a sacrifice, allow some animal to be lowered into the sewer first. And if none of those measures were found to be practicable, the simple precaution of tying a rope round the waist of the man who is the first to descend into the sewer would at all events prevent any loss of life.

Irish Workhouse Mortality.

The total number of deaths in the Irish workhouses in the fifty-two weeks comprised in the Local Government Board's report table has been 11,333. In the corresponding table in the last annual report the total number of deaths was 11,119, showing that there has been an increase of 214 deaths as compared with the number last year, and a decrease of 468 as compared with the number in the preceding year. The number of deaths by fever is 703 in comparison with 762 in the previous year, and with 663 in the year preceding. The deaths from small-pox in the workhouse hospitals were 41 in comparison with 142 in 1874-5, and with 110 in the preceding year. A decrease of 2,438 has taken place in the total number admitted in sickness during the year, and a decrease of 454 in the number suffering from fever and other dangeous contagious diseases.

Typhoid Fever in Kensington.

The following letter, in reply to the assertion of the Kensington Vestry that there have been no deaths in the present year from typhoid fever, has been sent to the Vestry Clerk by Sir Henry Cole :—"Immediately upon the receipt of the resolution of the Vestry of Kensington, dated the 26th of July, which asserted that no death had occurred from typhoid fever in South Kensington during the present year, I communicated with the General Registry Office of Births and Deaths. I found the Vestry had no authority for their statement, and learnt that in the sub-districts of Kensington Town and Brompton, including South Kensington, which is a modern local name, without definite boundaries, upwards of 24 deaths from fever had been registered during the 26 weeks ending the 1st of July, 1876. Of these 16 were certified as "typhoid," and this number is independent of deaths from diphtheria and diarrhœa, often connected with sewer gases. I beg leave to refer the Vestry to the "Annual Summary of the Causes of Death in London in 1875," printed and published by the Registrar-General, from which the Vestry will see that the deaths in 1875 from typhoid fever were 21 in Kensington and Brompton, so that the usual average death-rate from this disease would seem to be increasing. I have thus shown that deaths have been occurring without the knowledge of the Vestry or its medical officer. My statement that typhoid fever is chronic has foundation in fact. But it cannot be gainsaid that typhoid fever may be chronic, although it may not terminate in death, and it may exist, especially among well-to-do people, although the medical officer of health of the parish may be unacquainted with any cases of illness from that disease. I may also remark that the proportion in fever epidemics is usually one death in twenty cases. I will assume that the Vestry, like myself, will not mind a little trouble in this serious business, so I submit a suggestion which will enable the Vestry to improve the health and comfort of the Kensington inhabitants under their charge. I suggest that, with the view of affording to the medical officer that knowledge of the existence of typhoid fever which he does not at present possess, and until the law be improved, the Vestry should form a sanitary committee of the inhabitants of Kensington, who should report when cases of illness connected with sewer gases occur, and thus enable the medical officer of health and the parish surveyor to inquire into the state of the house drains where such cases are reported. As the Vestry communicated their resolution to the Metropolitan Board of Works, I request them to have the kindness to forward a copy of this answer to it."

Health of Watering Places.

At the Brighton Congress of the Social Science Association last year a resolution was passed recommending the council of the association to suggest to the local sanitary authorities of watering places the desirability of establishing a system by means of which owners of lodging-houses and hotels should be enabled to have their premises inspected and certified if found in a general healthy condition with reference to drainage and other sanitary arrangements. The council solicited the views of the local authorities on the subject, and received a number of answers in reply. The report has been forwarded to the local authorities of the several watering places and health-resorts in England and Wales.

We should regard the adoption of these suggestions as one of the best steps that could be taken to ensure a good sanitary condition of the many watering places which are every year becoming more and more crowded with visitors from all parts of the country. Although the system would be in a legal point of view a nominal one, a little reflection will show that if adopted by a majority of hotel and lodging-house keepers it would become virtually a compulsory one, inasmuch as the proprietors of the smaller establishments would be under the necessity of following the example of their neighbours, in order to free themselves from the suspicion which the non-possession of the proposed certificate would attach to their houses.

As we have noticed in our remarks upon the last Quarterly Return of the Registrar-General, the health of our watering-places may even now be very favourably compared with that of other towns, and there can be no doubt that if the above suggestions were carried out they would, as respects the prevalence of zymotic diseases, become the most healthy places in England.

The Registration of Diseases.

A committee of the British Medical Association reported at the meeting recently held in Sheffield that, notwithstanding certain suggestions they made to Government on this important subject in 1874, no further action has been taken in the matter either by the Government or the Local Government Board. The proposal for the registration of all cases of infectious disease met with very general acceptance, but one of the most important points for consideration was whether the onus of reporting the case should rest upon the householder or on the medical attendant. To be obliged to furnish information to a public official with regard to sickness occurring in a family might reasonably be resented by the medical profession. It would be regarded by many not merely as an unnecessary addition to their work, but as an inquisitorial test of the extent of their practice, and as leading to a breach of professional confidence that might cause much annoyance both to doctor and patient.

Then, again, the question of payment for information given was to be taken into account, and the cost of paying a medical man for every certificate he drew out would be so great as practically to be a bar to the whole enterprise. No such objections apply to the proposal to make the householder responsible for the declaration of the presence in his house of diseases likely to be injurious to the community. It would indeed be in accordance with the precedent set in the Public Health Act of 1875, which enacts (Clause 84) that the keeper of a common lodging-house shall give notice of the presence of fever or any infectious disease not only to the medical officer of health of the local authority, but also to the Poor-law relieving officer of the union or parish in which the house is situated.

For these reasons the committee expressly state that the proper person to make the return should, in their opinion, be the householder, and not the medical attendant upon the case. In the subsequent discussion on this Report, Dr. Sibson said he admired the sagacity with which the committee had not attempted to force the matter with a high hand either upon the public or upon the profession, but had, on the contrary, suggested a sound and practical method of carrying out the object which they had in view.

A serious outbreak of small-pox having occurred in one or two streets of Blackburn, the sanitary authorities have taken very prompt and decisive measures for stamping it out. These streets are barricaded, and the houses are being thoroughly saturated with disinfectants.

At a meeting of the West Derby (Liverpool) Guardians last week, it was resolved to ask the co-operation of the select vestry of the Toxteth Guardians for the establishment of a lunatic asylum for paupers near Liverpool, where the inmates could be maintained at a lower rate than in the present asylums.

Gunshot Wounds.

Dr. F. T. Bancroft, Denver, Colorado, reports a case (*Medical and Surgical Reporter*) in which a woman, married, seven months' pregnant, was accidentally shot by her husband. The ball (fired from an army revolver), conical in shape, entered between the second and third rib, about one inch from the sternum, passed through the right lung, and made its exit through the inferior angle of the scapula, about three inches below the spine. After leaving the body, its momentum was sufficient to carry it through an ordinary pine door. The accident was accompanied by severe hæmorrhage and shock. Treatment—free administration of opium internally, wounds dressed with warm whiskey-and-water. The dressings becoming agglutinated to the edges of the wound, and sealing them hermetically, were allowed to remain unchanged until recovery had nearly taken place. At full period she was delivered of a healthy child, the feet presenting. Nothing remarkable occurred during labour, and both mother and child did well.

Dr. N. R. Gordon, Cambell Hill, Ill. (*Ibid*), reports the case of a young man, æt. 20, who received a gunshot wound of the head. The parietal prominence was the part struck. The ball passed upward and backward, excavating a groove sufficiently large to admit the index finger. Coverings of brain penetrated. Small portion of brain tissue removed. When seen an hour after accident the patient was comatose, hæmorrhage excessive, radial pulse thirty per minute. There was a protrusion of brain substance as large as a hen's egg. Light pressure, aided by gravitation, effected a cure. Patient recovered in ten weeks. In two days he was sufficiently rational to relate how the accident occurred. At no time was there suppuration, or any untoward symptom.

Correspondence.

FRENCH BATHING PLACES—BOULOGNE-SUR-MER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I regret that the letter of Dr. Drysdale, my late colleague in London, printed in your columns so far back as June 28th, has only just come under my notice.

At this time of the year no doubt every one is asking which is the best seaside to resort to, and Dr. Drysdale says very truly that Boulogne is one of the most attractive, gay, and pleasant places accessible of all French watering-places, *but* that the defective way in which the contents of the drains are conveyed to the sea is a serious drawback.

Some two years ago I wrote you an account of how they were conveyed to the sea, or, rather, mostly into the harbour; and I must now relate what I can of what has been done since that time in the way of improving the same, and what is hoped to be done in the future. I am afraid there has been more talk than work done; and, like everything undertaken at Boulogne, from the Conseil Municipal down to the cobbler who repairs your boots, delay is the fashion.

The sewage question has been *à l'étude* for some ten years past, and is still so, the great difficulty in the way being a sufficient supply of water to carry the contents of the drains out to sea.

The water supply, till the commencement of the present year, averaged sixteen litres per head per diem; it has since then been increased to over twenty litres, and this has been done by the construction of two reservoirs, one on the high ground on the route de Calais, and another at Chatillon, the other side of the river Liane; while the latest increased water supply has been derived from La Cachaine at Coudette, near Pont de Briques.

The project, however, which is of the most importance, and which is, of course, the most delayed, is the supply from Tingry, near Samer, on the route de St. Omer. This would raise the supply to the town to 140 litres a day per head.

One improvement has been made, however, in conveying the sewage, which fell into the harbour opposite the fish market, by means of a covered drain, into the middle of the same—in fact, into the course of the Liane itself, where the water always flows. This will be of some use for the present, though *when* the main drainage along the quay is carried out it will be of no further use.

The water-supply, collecting of sewage, and carrying out to sea, will cost 2,000,000 francs, and this is also a serious consideration.

One little incident about the drainage of Boulogne is, I think, worth recording. About a month ago, on a question of supply for some educational scheme in the Conseil Municipal, a member happening to say that he thought the drainage question was of more importance, was—well! not listened to.

With all its defective drainage, however, Boulogne is a healthy place. I have lived here over four years, and in course of practice I do not remember any special epidemic during that period; the sea-breezes, the fact of the tide running so far into the town, and by means of sluice-gates the harbour being sluiced at the highest tides for three or four days twice a month, together with the permeable soil on which the houses are built, are perhaps the reasons for the same; while the death-rate is only 22·5 in 1,000, being lower than that of many English watering-places, such as Scarborough, Whitby, &c., which number 23·4 and 24·2 respectively per 1,000. The rate I mention is that taken for a period of ten years, from 1864 to 1875,—1866, the cholera year, and 1871, the year of the Franco-Prussian war, being omitted. I believe our death-rate is almost the same as that of Margate and Brighton. There are, of course, some quarters where the death-rate is higher than in others, the same as there are large towns where mortality is very great, which, taken in the average of a whole country, merge into a very low percentage in favour of the latter; thus, in London the rate is 2·24, while that of England is 2·14, Paris 2·30, France 2·16, Vienna 3·28, Austria 2·86, &c.

As regards sanitary measures, I am sure Boulogne is well looked after, thanks to M. de Poilly, the inspecting engineer, who causes "heavy coal-tar oil" to be placed at proper times in proper places, and conveyed into the drains. This gentleman has published his experience with the results of experiments lately made with *l'huile lourde de houille* (which is the residue of coal-tar oil after having been submitted to a high temperature, its density being greater than that of water and boiling point of between 210° to 300° (*c*)), in a pamphlet, or rather a resume of a lecture delivered by himself before the Société Academique on October 6th, 1875.

There is no doubt that this substance is one of the best disinfectants, if not the best, at present known, while sulphate of iron acts best as a disodorant. All I can add is, that I trust that this subject having been now alluded to in a medical journal for a second time, may rouse up the wise men of Boulogne-sur-Mer to take steps to put an end to the evil alluded to by Dr. Drysdale, and carry their sewage out to sea as soon as possible, perhaps before the projected sub-channel tunnel is completed, and that they will then derive more benefit by the influx of visitors who will doubtless flock here to see that great work, and be greatly surprised that the "*smell of the harbour at low water is not disagreeable.*"

I am, Sir, yours faithfully,
SIDNEY CHATER.

16 Rue des Vieillards, Boulogne-sur-Mer,
Aug. 15, 1876.

THE PHYSICAL PSYCHOLOGY OF CRIMINALS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I ask your permission for the sake of that advancement in scientific knowledge which we desire in common, to make a few observations on the leading article which appeared in your issue of the 2nd inst., entitled "The Physical Psychology of Criminals."

With the general scope of that article I do not desire to grapple at present, but wish to direct attention to some of the points adduced in argument with which I feel it impossible to agree, and which if allowed to pass unchallenged, may, I think, be productive of mischief.

I trust, sir, that it is far from my desire to magnify, however slightly, the too little knowledge we really possess of the human and comparative structure of the brain; but, on the other hand, it is not right that these facts which the united labours of histologists have brought to light should pass unacknowledged, or be shorn of their undoubted importance. And if I venture to call in question some of the remarks contained in your article referred to, it is because being tolerably familiar with the subject on which I write, and knowing the great importance of the question at issue, I desire the facts to be fairly and accurately stated.

I find that the statements which have given rise to the present letter are for the most part contained in a sentence in your leader which I shall quote verbatim. It is as follows:—"Mr. Lockhart Clarke has very carefully investigated the cortical substance of the brain, and yet neither he nor any other physiologist has described any marked difference of structure between the vesicular matter of one part of the cerebrum and that of another, between that of the infant and that of the adult, or even between that of man and that of the higher quadrumana."

I hope to show that the above statement is inaccurate, and with every feeling of respect towards the able writer of your article, feel called upon to give it my most unqualified opposition. I shall show, on the authority of Dr. Lockhart Clarke himself, and on that of other histologists, that the minute structure of the cerebral cortex *does* present decided and important variations in different parts; that the minute structure of the infant's brain *does* differ from that of the adult; and lastly, although on this point I am less decided, that these are structural differences between the human organ and that of the higher quadrumata.

So far back as 1863 ("Proceedings of the Royal Society," vol. xii.), and again somewhat later (Maudsley's "Physiology and Pathology of Mind"), Dr. Clarke showed that the nerve cells at the tips of the occipital lobes differ in their form, size, and to some extent also in their arrangement, from those of the vertex of the brain. He showed that in the marginal gyrix there is a peculiarity of structure, as also in the internal orbital convolutions and in the Island of Reil, and he concludes that "not only in different convolutions does the structure assume to a greater or less extent a variety of modifications, but even different parts of the same convolution may vary with regard either to the arrangement or the relative sizes of their cells. (Maudsley's "Physiology and Pathology of Mind," page 63). The observations of Lockhart Clarke have been confirmed and extended by such men as Thomas Maynert, Arndt, and many others (Stricker's "Num. and Comp. Histology"). If it be said that the differences of structure are so slight as to be doubtful, I reply that they are indeed often slight, but they are not doubtful; and add further, that in such an organ as the brain it may fairly be concluded that the most trifling modifications of structure *apparently* may have most profound significance.

It is not easy, indeed, to see how it can be maintained that little difference exists histologically between the structure of the tips of the occipital lobe and that of the frontals or other parts, when, as a matter of fact, the practised observer can single out with unerring certainty a section taken from the former situations.

Is it the case in the second place that no difference can be detected in the minute structure of the brain in infancy as compared with the adult. Assuredly it is not the case. The early fœtal brain of man and animals consists of an uninterrupted nucleated network (L. Clark, *loc. cit.*, 1863); at birth the structure is naturally more developed, but still certainly not similar to the fully grown brain. I have shown, as I believe ("West Riding Asylum Reports," vols. iii. and iv.) that in the infant the number of the cell branches is very small as compared with the corresponding bodies in the adult, and this alone is a most important distinction.

Lastly, can no histological distinction be drawn between the cerebral structure in man and in the higher apes? Let it be at once admitted that the similarity is most remarkable, and that Dr. Clarke is correctly quoted as saying that he has not been able to distinguish any difference whatever. Nevertheless, I venture to affirm that the similarity is not complete, and in support of my statement it is necessary, in the absence of other authorities, that I should refer again to my own researches.

In a thesis presented to the University of Edinburgh (1875) I advanced the opinion, as the result of a careful examination of several apes' brains, that in them the nerve corpuscles of the cerebral cortex were smaller in size than in man. It is right I should add, however, that my observations were not founded on the highest apes. In January of the present year

I described fully (*Journal of Mental Science*) the histological structure of the cerebral cortex of the chacuca, one of the largest and most powerful of the baboons. I can here only refer to one (and the most important) conclusion to which I was led—viz., that in the chacuca the number of the cell branches—*i.e.*, the *extent of the cell connections is less* than in man.

Believing the above to be the case, knowing further the condition of the cerebral cells in the fœtal and infantile brain, believing that in old age one of the first changes to occur in the nerve cells is a loss, in a greater or less degree, of their branches ("West Riding Asylum Reports," vols iii. and iv.), is it too much to infer, as I have ventured to do, that there may be an intimate relation between richness of the sub-cellular connections and elevation with activity of function ?

I have to apologise for the length of this letter, for which I can only plead the great importance of the question at issue.

I am, Sir, yours obediently,
HERBERT C. MAJOR, M.D. Edin.
West Riding Asylum, Wakefield.

THE KEIGHLEY GUARDIANS AND IMPURE VACCINE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The conduct of the Keighley Board of Guardians has suggested to me the justice of calling attention through your columns to facts which have come under my observation, and which have tended (in my opinion) to palliate the conduct of anti-vaccinators.

That the prevailing method of vaccinating from arm to arm is attended with serious risks to health none can doubt, even when the utmost caution is exercised. I have known seven cases of vaccino-syphilis to result from "bad infection," and have seen a formidable axillary abscess follow from the same cause, although in the cases in question the utmost care was adopted to prevent the blood of the vaccinefer contaminating the lymph, there being at the same time no appearance of any *sensible* disease, although, as events proved, syphilis and other morbid affections lay latent in the system.

I am no vaccino-phobiac. I hold it to be the duty of the State to rigidly enforce vaccination, but at the same time it is equally the duty of the State to afford every guarantee that the operation shall be performed *without any risk of bad infection*, which object can be best secured by the establishment of a "National Vaccine Paddock," as is the case in other countries. In the absence of a supply *pure from the heifer*, passive resistance to the vaccination laws is rather to be approved than censured. The establishment of a vaccine paddock has been recently mooted in England, but the matter has not up to the present received public notice in Ireland.

I remain, Sir, yours very truly,
FRANK THORPE PORTER.

◆

Analytical Reports.

HENRI NESTLE'S "MILK FOOD."

THIS food, on being submitted to analysis, gave the following results :—

Starch, cellulose, and gum	38·81
Ash	1·49
Nitrogenous matter	8·00
Moisture	2·45
Fat	6·25
Saccharine matter	43·—
	100·00

The starch in this sample appeared to be wheat starch, the granules of which had been broken by heat. The taste had a character indicative of a certain amount of cooking, but still very pleasant. From the above analysis it would appear that this preparation was very nearly a compound of one-third wheat starch, one third sugar, and one-third the dried ingredients of milk. The starch is in a form easy of assimilation, and the whole makes a food of a most agreeable and pleasant nature for children.

DR. NICHOL'S "FOOD OF HEALTH."

DR. NICHOL'S "Food of Health," when examined, was found to consist of—

Starch, cellulose, &c.	84·8
Moisture	11·5
Nitrogen	1·8
Ash	1·8
	99·9

This 1·8 of nitrogen would represent about 14·5 per cent. of gluten.

Dr. Nichol's "Food of Health," therefore, agrees almost identically with whole meal in composition—that is to say, wheat flower with the bran—but from the microscopic examination it seems deficient in the part which is generally known under the name of "pollard," or the portion intermediate between the true starch and the bran.

The statements contained in the advertisement puffs are not justified except so far as they are applicable to whole wheaten meal, of course making due allowance for the romantic colouring of the disciples of the "staff of life." Whether Dr. Nichol's—who, we may remark, has no legal right to the title of "Dr." in this country—is justified in asking 8d. per pound for wheaten meal is a question about which the consumer can draw a fair inference on consulting the market quotations of the day.

◆

Medical News.

University of London.—Certain changes have recently been made in the regulations for the University of London's degrees of Bachelor and Doctor in Science. The committee to which the revision of the regulations for examinations in art, science, and laws, was entrusted, says, with regard to the degree of Bachelor of Science :—"It has come to be generally felt that scientific knowledge, to be real, must be practical as well as theoretical, and that a thorough knowledge limited to a comparatively small range is preferable to a slighter acquaintance spread over a more extended area; and it is the general experience of teachers that there is, from the commencement of their academical course, such a decided preference on the part of nearly all students of science for either the physical or the biological group of subjects that the attention of each student is given to one group almost to the exclusion of the other. It was further urged that the hiatus is too wide between the almost elementary knowledge of the several departments of science required in the Bachelor's examination and the very high attainment in some limited department which is required as the qualification for the Doctorate; and that it would be extremely desirable that this hiatus should be narrowed by limiting the number of subjects to be brought up by candidates for the B.Sc. degree, and proportionally raising the standard of proficiency required. After much consideration and communication with their scientific advisers, the committee have arrived at the conclusion that it would be desirable rather to diminish the number of subjects which each candidate should be required to bring up at the second B.Sc. examination, than to exact anything short of the 'competent knowledge' of each subject for which these programmes provide. They are further of opinion that each candidate, instead of being required to include either the whole or a part of the subjects he selects in one or other of the before-mentioned groups, should be allowed a free option among all of them, so as to combine them in any way that may best suit his taste and ulterior objects—thus leading him onwards to the still higher specialisation of the Doctorate. Acting on this principle, the committee have framed a new set of regulations for the degree of Bachelor of Science, which they now submit to the consideration of the senate. In the first examination, which every candidate will be required to pass, while the programmes in mathematics, experimental physics, and inorganic chemistry have been carefully revised, little fundamental change has been made in them. In place of the superficial acquaintance with both zoology and botany formerly required at this examination, the committee now recommend a single examination (written and practical) in general biology, in which a more thorough knowledge shall be required of the simplest forms and elementary phenomena of animal and vegetable life, such as is now made the basis of the teaching of some of the most distinguished professors in each department. Thus the student who may be intending to devote himself specially to physical or chemical science will be brought to apprehend the general conceptions common to the two great organic kingdoms, without being required to master the specialities of either; and the student who intends to present himself at the second B.Sc. examination in either physiology, zoology, or botany, or all combined, will have laid the best foundation for those special studies in the study of general biology. The regulations for the second B.Sc. examination, on the other hand, are framed with the view of allowing the candidate to bring up any three of the following nine subjects :—(1) Pure mathematics, (2) mixed mathematics, (3) experimental physics, (4) chemistry, (5) botany, including vegetable physiology, (6) zoology, (7) animal physiology, (8) physical geography and geology, (9) logic and psychology. It is intended by the Committee that the examinations in these several subjects should be, as nearly as may be, on the same grade, as to the amount of attainment they require. It is understood that the Senate has revised the regulations for the science degrees in accordance with those recommendations by the committee. In addition, that in the Matriculation Examination, which forms the basis of the science curriculum, German may now be taken in substitution for Greek. In regard to the Doctor's degree, a change has been made in favour of candidates who prolong the interval between their first and second examinations for the degrees of Bachelor from one year to two or more, as such will be allowed to come up for the degree of Doctor of Science within a year of their attaining the degree of Bachelor.

◆

THE ADVISABILITY OF LEGISLATIVE RESTRICTIONS FOR HABITUAL DRUNKARDS.

Report of the Committee of the British Medical Association.

THE committee appointed to consider the advisability of legislative restrictions for habitual drunkards by the Committee of Council, on July 13th, 1875, have given the resolution passed at the last Annual General Meeting of Members at Edinburgh their particular attention. They have held six meetings, several members attending from distant parts of the country, but hitherto have been unable to take any decided action.

The committee inquired of the Home Secretary as to whether the Government intended to bring in a Bill to deal with the subject. He has informed us "That the Government had no intention of dealing with the question during this Session, and that any Bill on the subject would receive due consideration when its details could be examined."

The committee have also communicated with the Medical and several other members of Parliament, and have received encouraging replies from nearly all, but have not yet succeeded in finding a leader as a successor to the late Mr. Dalrymple willing to press the subject upon the attention of the House of Commons.

The committee also find that the outer world have mistaken notions of the objects to be attained, and are suspicious of any action which appears likely to interfere with the liberty of the subject. To meet this difficulty your Committee have sought and obtained the co-operation of the Social Science Association, and have also prepared a petition for signature by members of the profession, as well as the general public, which sets forth objects to be sought for as under :—

Unto the Honourable the Commons of Great Britain and Ireland in Parliament Assembled, the Humble Petition of the Undersigned Sheweth,

That habitual drunkenness prevails extensively among both sexes, and all clases of society ; is one of the most fruitful sources of domestic misery, of disease, pauperism, and crime ; and calls loudly for the adoption of some remedial measure.

That the right of the State to deprive of their liberty, and even to subject to fine and imprisonment, not only the "drunk and disorderly," but the "drunk and incapable," has been long recognised by law, and is continually exercised throughout the realm ; while more recently the Licensing Act, 1872, gives power to the police to take proceedings against persons found drunk, although neither incapable nor disorderly.

That the merely penal treatment of drunkenness, by committal to prison for short periods, far from influencing for the better the habitual drunkard, is shewn by the evidence taken before the Select Committee of the House of Commons, 1872, to be "worse than useless ;" confirms him in his evil ways, by utterly destroying his self-respect, and rendering him reckless of consequences ; and thus runs counter to the whole tendency of recent legislation, which aims at the reformation as well as the correction of the offender.

That your petitioners fail to perceive any valid reason why this right of State interference with his personal liberty, so long recognised and so constantly put in force, should not be exercised for the reformation of the habitual drunkard.

That strong testimony was given in 1872, before the Select Committee of the House of Commons, that the treatment of habitual drunkards in Reformatory Institutions has been followed both in this country and in the United States of America, by the recovery of a large percentage of those subjected to it.

That the power of compulsory committal and detention for a term not exceeding a year, as recommended by the Select Committee of 1872, was, by the evidence taken before the committee, shown to be in operation in various parts of the United States of America, and to be unattended by any evil consequences, the silent influence of the law inducing many voluntarily to submit themselves to the salutary discipline of the Reformatory Institutions for the time required to effect a cure.

May it therefore please your Honourable House to take this important subject into your careful consideration, and to pass into a law a measure for the control and cure of habitual drunkards.

And your petitioners will ever pray, &c.

Your committee recommend that the petition be printed in the Journal, and also distributed to the Secretaries of the Branches, requesting them to obtain signatures or place them in the hands of those likely to assist the movement, and then forward them to their representatives in Parliament, for presentation as early as possible in the next Session, by which time your committee hope that either the Government or some private members may be induced to bring the subject to the notice of the House of Commons, and give effect to the resolution proposed at the Edinburgh meeting.

Your committee suggest that they be re-appointed for the purpose of continuing their efforts in the same direction.

ALFRED CARPENTER, M.D., Chairman.

Sheffield, August 3rd, 1876.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

SUBSCRIBERS who have not yet sent in their subscriptions for last year are respectfully reminded of the omission.

DR. DUNCAN.—The work of Surgeon-General Gordon entitled "The Military Hygiene and Surgery of the Franco-Prussian War" will be the most suitable if you are setting out for the war in the East. Surgeon Porter's pocket-book would also be useful.

DR. MAJOR.—Your communication arrived last week after we had "made up" for press. You will find it inserted in our present number.

"THE BRAVO CASE."

To the Editor of the MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—May I trespass on your columns to make a few observations on this interesting case.

From the evidence of the gentlemen who performed the *post-mortem*, as well as from the general evidence produced at the inquiry, it appears clear to me that Mr. Bravo did *not* die from the effects of tartar emetic, that tartar emetic was not administered with the intention of causing his death. The question then comes for what reason was it given? I will answer this by showing why it might be given, and in doing will refrain from any allusion to names, &c. Mr. Bravo was no doubt obnoxious to a good many persons whose names appear as witnesses, and my idea is that his removal being decided on, some subtle poison was administered, and that the person by whom that poison was given (as is almost invariably the case) having repented of the evil when *too late*, made an attempt to obviate the action of the poison, as far as lay in their power, by administering an emetic. That tartar emetic, perhaps, in the form of *antimonial wine* was given with the only result (as it turned out) of unintentionally cloaking the real poison and leading the authorities on a wild goose chase.

I am, Sir,
Yours faithfully,
Waterford. Wm. Donovan.

[Our correspondent's major premise, which is clear to his comprehension, that Mr. Bravo did not die of tartar emetic poison or of that drug administered with *malice prepense*, is by no means clear to ours. The general verdict is the direct reverse, and, if correct, renders impossible our correspondent's theory.—Ed. M. P. & C.]

A Subscriber inquires whether any bye-law at any time existed in the Apothecaries' Hall in Ireland forbidding any person other than an apothecary to compound medicines in an hospital. The Apothecaries' Act distinctly forbids any one excepting an L.A.H. of Dublin to exercise the functions of an apothecary in Ireland. This prohibition was in some respect modified by the Medical Act of 1858, under which it has been ruled that a duly qualified medical practitioner might compound, though even this point is not beyond legal dispute. Although the law is quite clear that until the passing of the Irish Pharmacy Act none but an apothecary or medical practitioner could compound medicines in Ireland; yet the function of apothecary to a county infirmary continues—as we believe quite illegally—to be discharged in Galway by an unqualified person under the patronage and by the act of the surgeon to the institution.—Ed. M. P. & C.

Nutbrown does not give his name and address, and according to our rule we cannot give space to, or answer his communication. He had better consult a practitioner who has made the skin a special study.

Dr. Leeson is thanked.

MEDICAL ETIQUETTE.

To the Editor of the Medical Press and Circular.

Sir,—Afford me your opinion on the following case:—

I am considered the medical adviser of a lady whenever required. While out of town for two days the lady was taken suddenly ill, and I was sent for. Not to be found at home a general practitioner was called in. He was informed of my absence. Of my return the lady was informed, and the practitioner also, when the family suggested myself in further advice. The general practitioner, so I was told, told the patient all the physicians in London could not do more for her, and hoped the lady was quite satisfied with him. Is this the "*correct practice* of general practitioners?" Certainly no physician would act thus.

A Pure Physician.

[The conduct of a general practitioner acting as described by our correspondent strikes us as neither in accordance with medical etiquette nor with the good taste presumed to be current amongst gentlemen, nor even with discretion on his own part. In so acting a general practitioner assumes a great responsibility, and leaves on the patients' mind an inference of egotistical confidence in his own merits which will be sure sooner or later, whether the case be satisfactory or not, to react to the practitioner's discredit. It is, however, unhappily nothing very unusual in the annals of our profession for one practitioner to discourage a reference to a medical brother whom he may regard as a competitor.—Ed. M. P. & C.]

Dr. J. P. Myles, Parsonstown.—Your letter shall appear in our next issue.

Dr. Laffan, Cashel.—The Report is a Blue-book, and if to be had at all, can only be procured from Hansards, Great Queen Street, London, W.C., or through Thom, of Abbey Street. Copies are only to be seen in Dublin in the Libraries of the University and the College of Surgeons, and of one or two individuals. The title of the book is the "Report of the Commission on Dublin Hospitals."

Dr. L.—The Public Health (Ireland) Bill will be under the consideration of a joint committee of the Colleges of Surgeons and Physicians, the [illegible] Medical Association, and the Sanitary Association who will examine its provisions and suggest any necessary amendments between this and the reopening of Parliament next February. A sanitary conference such as you suggest seems, therefore, to be unnecessary, and we doubt that the matter is of sufficient personal interest to individuals to make such a conference a numerical success.—Ed. M. P. & C.

VACANCIES.

North Staffordshire Infirmary. House Surgeon at a salary of £120, and a House Physician at £80 per annum; each with board and residence. Applications to the Secretary at Hartshill, Staffs.

Northampton General Infirmary. Surgeon. Honorary. Applications to the Secretary.

London Hospital. Aural Surgeon and Lecturer on Aural Surgery. Applications to the House Committee, Whitechapel, E.

◆

APPOINTMENTS.

Cane, H., M.R.C.S., L.R.C.P., House Physician to the Westminster Hospital.

Carter, A. H., M.D., an Extra Acting Physician to the Birmingham and Midland Free Hospital for Sick Children.

Donovan, Dr. Wm., Medical Officer to the Government Postal and Telegraphic Departments, Waterford.

Price, W. H., M.R.C.S.E., Medical Officer to the Penmachno Slate Quarries.

[illegible], J. A., L.K.Q.C.P.I. and L.M., L.R.C.S.I., Medical Officer for the Ahascragh Dispensary District of the Ballinasloe Union, Co. Galway.

[illegible], A. H., M.B., C.M., Medical Officer for No. 2 District, and Medical Officer to the Workhouse of the Mere Union, Wilts, and Medical Officer of Health for the Mere Rural Sanitary District.

◆

Deaths.

Cathcart.—On Aug. 8, at Ballybay, James Cathcart, C.M., aged 63.

Grantham.—On Aug. 4, at Falsgrave, Scarborough, Thomas Payne James Grantham, M.R.C.P.L., aged 62.

Ryan.—On Aug. 7, at Lonsdale Square, Islington, John Ryan, M.D., LL.D., aged 66.

GENERAL NURSING INSTITUTE for TRAINED HOSPITAL NURSES.
5 Henrietta Street, Covent Garden, W.C.
A. EBSWORTH, F.R.C.S., Director.

ROYAL COLLEGE OF SCIENCE FOR IRELAND,
STEPHEN'S GREEN, DUBLIN.

SCIENTIFIC AND TECHNICAL EDUCATION.

This College supplies a complete Course of Instruction in Science, applicable to the Industrial Arts, especially those which may be classed broadly under the heads of Chemical Manufactures, Mining, Engineering, and Agriculture.

A Diploma of Associate of the College is granted at the end of the Three Years' Course.

There are Four Royal Scholarships of the value of £50 each yearly, with free education, including Laboratory Instruction, tenable for two years. Two become vacant each year. They are given to Students who have been a year in the College.

The Fees are £2 for each Course, or £10 for all the Courses of each year, with the exception of Laboratory Practice.

Chemistry (Theoretical and Practical), Metallurgy, &c.—Professor Galloway, F.C.S.
Mathematics, Mechanics, and Mechanism.—Prof. Hennessey, F.R.S.
Descriptive Geometry, Drawing, Engineering, and Surveying.—Professor Pigot, C.E., M.R.I.A.
Experimental Physics (Theoretical and Practical).—Prof. Barrett, F.R.S.E., F.C.S.
Mining and Mineralogy.—Professor O'Reilly, C.E., M.R.I.A.
Agriculture.—Professor Davy, M.D., M.R.I.A.
Botany.—Professor M'Nab, M.D.
Zoology.—Professor Leith Adams, M.B., F.R.S.
Geology.—Professor Hull, M.A., F.R.S.
Palæontology.—Mr. Baily, F.G.S.

The Chemical and Physical Laboratories are open daily for Practical Instruction.

The Session commences on Monday, October 2nd.

Programmes may be obtained on application to the Secretary, Royal College of Science, Stephen's Green, Dublin.

FREDERICK J. SIDNEY, LL.D., Secretary.

THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.

Patron:—H.R.H THE PRINCE OF WALES.

This Institution was founded in 1869, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develop the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £40 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote.

Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c. can be had at the office,

40 MOLESWORTH STREET, DUBLIN,
W. O'NEILL, Secretary.

THE LONDON HOSPITAL MEDICAL COLLEGE.

The next WINTER SESSION will commence on MONDAY, OCTOBER 2nd, 1876, when the Introductory Lecture will be given by Dr. Andrew Clark, Senior Physician to the Hospital.

The perpetual fee to Lectures and Hospital Practice, with two years' Practical Anatomy, is 90 guineas if paid in one sum, or 100 guineas if paid by three instalments. Special entries can be made to Lectures or Practice.

The Hospital contains about 800 beds. The In-patients during 1875 were 5,804, and the Out-patients, 40,717.

1, 2- Two Entrance Science Scholarships, value £60 and £40;
3, 4. and two Buxton Scholarships, value £30 and £20, will be offered for competition at the end of September. Entries for the above must be made on or before the 20th September.
5. A Scholarship, value £20, in Human Anatomy, for first-year's Students.
6. A Scholarship, value £25, in Anatomy, Physiology, and Chemistry, for first and second year's Students.
7. A Hospital Scholarship, value £20, for Clinical Medicine.
8. A Hospital Scholarship, value £20, for Clinical Surgery.
9. A Hospital Scholarship, value £20, for Clinical Obstetrics.

A Prize of £5 to the Student who has attended most Midwifery Cases during the preceding twelve months. The Duckworth Nelson Prize, value £10, for Practical Medicine and Surgery (Biennial). Money Prizes to the value of £60 given annually by the House Committee, for zeal in Dressing Out-patients and knowledge of Minor Surgery.

For particulars as to Appointments see the Prospectus, which will be forwarded on application to the Secretary, Turner Street, Mile End, E.

Greatly increased facilities are now afforded by adjacent railways and tramways for rapid transit from the neighbourhood of the Hospital to other parts of London. The East London Railway Company's station is directly opposite the Hospital. Lodgings can be obtained in healthy localities in the immediate vicinity of the Hospital, at a very reasonable charge.

UNIVERSITY COLLEGE, BRISTOL.

MEDICAL SCHOOL.

The WINTER SESSION will commence on MONDAY, October 2.
Prospectuses may be obtained on application to
GEORGE F. BURDER, M.D., Hon. Sec.
Medical School, Old Park, Bristol,
August, 1876.

ST. THOMAS'S HOSPITAL, ALBERT EMBANKMENT, WESTMINSTER BRIDGE, S.E.—The MEDICAL SESSION for 1876 and 1877, will commence on MONDAY, the 2nd OCTOBER, 1876, on which occasion an Address will be delivered by Mr. FRANCIS MASON, at Four o'clock.

Gentlemen are informed that the Admission Fees to Practice and to all the Lectures may be paid in one of two ways:—

1st. One Hundred Guineas, paid on entrance, entitle a Student to unlimited attendance.

2nd. Payment by three instalments, namely, of £40, at the beginning of the first year, £40 at the beginning of the second year, and £30 at the beginning of the third year, entitles a Student after payment of the third instalment to unlimited attendance.

Special Entries may be made to any Course of Lectures or to the Hospital Practice; and a modified Scale of Fees is arranged for Students entering in their Second, Third, or any subsequent year.

Private Classes for Students preparing for Matriculation, and for the Preliminary Scientific Examination, and M.B. Examinations, of the University of London, or for other Examinations, are conducted by members of the Staff, and embrace instruction in Chemistry, Natural Philosophy, Botany, and Comparative Anatomy, Physiology, Anatomy, and Materia Medica. Gentlemen can attend these Classes without becoming Students of the Hospital.

PRIZES AND APPOINTMENTS FOR THE SESSION.

First Year's Prizes. Winter.—Entrance Scholarships of £60 and £40 awarded after an Examination in Physics, Chemistry, Botany, and Zoology. The Wm. Tite Scholarship of £30. College Prizes—£20 and £10. Summer Prizes—£15, £10, and £5.

Second Year's Prizes. Winter.—The College Scholarship of 40 guineas, tenable for two years. College Prizes—£20 and £10. Summer Prizes—£15, £10, and £5. The Assistant Dresserships, Clinical and Obstetric Clerkships are open to Students who have passed the Primary Examinations at the Royal College of Surgeons.

Third Year's Prizes. Winter.—£20, £15, and £10. In-Patient Clinical Clerkships and Dresserships.

The Cheselden Medal is awarded after a Special Examination in Surgical Anatomy and Surgery. The Mead Medal, awarded after a Special Examination in Practical Medicine and Hygiene. The Solly Medal, with a Prize of at least 10 Guineas, for a collection of Surgical Reports. The Treasurer's Gold Medal, for General Proficiency during the entire course of Study. The Grainger Testimonial Prize, for Physiological Essay illustrated by preparations. The Two House Physicianships. The Two House Surgeoncies. The Resident Accoucheurships.

A Medical and a Surgical Registrarship, at a honorarium of £40 each, is awarded to Third or Fourth Year's Students.

MEDICAL OFFICERS.

Honorary Consulting Physicians—Dr. Barker and Dr. J. Risdon Bennett.
Honorary Consulting Surgeon—Mr. Frederick Le Gros Clark.
Physicians—Dr. Peacock, Dr. Bristowe, Dr. Murchison, Dr. Stone.
Obstetric Physician—Dr. Gervis.
Surgeons—Mr. Simon, Mr. Sydney Jones, Mr. Croft, Mr. MacCormac.
Ophthalmic Surgeon—Mr. Liebreich.
Assistant Physicians—Dr. Ord, Dr. J. Harley, Dr. Payne.
Assistant Obstetric Physician—Dr. Cory.
Assistant Surgeons—Mr. F. Mason, Mr. W. W. Wagstaffe, Mr. A. O. MacKellar.
Dental Surgeon—Mr. J. W. Elliott.
Assistant Dental Surgeon—Mr. W. G. Ranger.
Resident Assistant Physician—Dr. Sharkey.
Resident Assistant Surgeon—Mr. Clutton.
Apothecary—Mr. S. Plowman.

LECTURERS.

Medicine—Dr. Bristowe and Dr. Murchison.
Surgery—Mr. Sydney Jones and Mr. MacCormac.
General Pathology—Dr. Payne.
Physiology and Practical Physiology—Dr. Ord and Dr. John Harley.
Demonstration in Physiology—Dr. T. Cranstoun Charles.
Descriptive Anatomy—Mr. Francis Mason and Mr. W. W. Wagstaffe
Anatomical Demonstrations in the Dissecting Room—The Anatomical Lecturers, Dr. R. W. Reid and Assistants.
Special Anatomical and Microscopical Demonstrations—Mr. Rainey
Practical and Manipulative Surgery—Mr. Croft and Mr. MacKellar.
Chemistry and Practical Chemistry—Dr. A. J. Bernays.
Midwifery—Dr. Gervis.
Physics and Natural Philosophy—Dr. Stone.
Materia Medica—Dr. Payne.
Forensic Medicine—Dr. Stone.
Comparative Anatomy—Mr. C. Stewart
Ophthalmic Surgery—Mr. Liebreich.
Botany—Mr. A. W. Bennett.
Dental Surgery—Mr. J. W. Elliott and Mr. W. G. Ranger.
Demonstrations of Morbid Anatomy—Dr. Greenfield.
Lectures on Morbid Anatomy and Practical Pathology—Dr. Greenfield.
Mental Diseases—Dr. Wm. Rhys Williams.
State Medicine—Dr. Alfred Carpenter.

W. M. ORD, M.B., Dean.
R. G. WHITFIELD, Medical Secretary.

Any further information required will be afforded by Mr. WHITFIELD.

CHARING CROSS HOSPITAL MEDICAL SCHOOL.

ENTRANCE SCHOLARSHIPS.

Two Entrance Scholarships of the value of £30 and £20 respectively, tenable for one year, will be awarded annually in the first week in October, after a competitive examination in the following subjects:—Compulsory: English, Latin, French or German, Mathematics. Optional (only one of which may be selected): Chemistry, Mechanics, German, or French. The subjects (as regards extent and the authors selected) will be the same as those chosen for the Matriculation Examination of the University of London in June, 1876.

Candidates must give notice of their intention to compete on or before Saturday, September 16th, 1876. FRANCIS HIRD, Dean.

SCHOLARSHIPS in SCIENCE.—ST. BARTHOLOMEW'S HOSPITAL and COLLEGE.—A Scholarship of £100 open to Students who have not entered at any Metropolitan Medical School, will be offered for competition on September 27. Subjects:—Chemistry, Botany, Zoology, Physics. An Exhibition of £50 in the same Subjects, and One of £40 in the Subjects of Preliminary Education, open to Students who have entered at the Hospital in October, will be competed for in October. For particulars, apply personally, or by letter, to the Warden of the College, St. Bartholomew's Hospital, Smithfield, E.C.

GUY'S HOSPITAL.—The Medical Session commences on MONDAY, OCTOBER 2nd.

MEDICAL OFFICERS.

Consulting Physicians—Sir W. Gull, Bart., M.D., D.C.L., F.R.S.; G. Owen Rees, M.D., F.R.S.
Physicians—S. O. Habershon, M.D.; S. Wilks, M.D., F.R.S.; F. W. Pavy, M.D., F.R.S.; W. Moxon, M.D.
Assistant Physicians—C. Hilton Fagge, M.D.; P. H. Pye-Smith, M.D.; Frederick Taylor, M.D.
Consulting Surgeons—J. Hilton, Esq., F.R.S.; E. Cock, Esq.
Surgeons—J. Cooper Forster, Esq.; Thomas Bryant, Esq.; Arthur E. Durham, Esq.; H. G. Howse, M.S.
Assistant Surgeons—N. Davies-Colley, M.C.; R. Clement Lucas, B.S.; C. H. Golding-Bird, M.B.; W. H. A. Jacobson, Esq.
Consulting Obstetric Physician—Henry Oldham, M.D.
Obstetric Physician—J. Braxton Hicks, M.D., F.R.S.
Assistant Obstetric Physician—A. L. Galabin, M.D.
Ophthalmic Surgeon—C. Bader, Esq.
Assistant Ophthalmic Surgeon—C. Higgens, Esq.
Dental Surgeon—S. J. A. Salter, M.B., F.R.S.
Assistant Dental Surgeon—H. Moon, Esq.
Aural Surgeon—W. Laidlaw Purves, Esq.
Medical Registrars—Frederick Taylor, M.D.; J. F. Goodhart, M.D.
Surgical Registrar—Frederic Durham, Esq.
Apothecary—James Stocker, Esq.

The Hospital now contains 695 beds, and includes wards for obstetric, ophthalmic, and other special departments.

In connection with the Lying-in Charity, about 2,500 cases are annually attended by the Students.

Number of Patients relieved during the year, about 91,000.

LECTURES, DEMONSTRATIONS, AND PRACTICAL COURSES.

Medicine—Dr. Habershon and Dr. Wilks.
Clinical Medicine—Dr. Habershon, Dr. Wilks, Dr. Pavy, and Dr. Moxon.
Surgery—Mr. Bryant and Mr. Arthur E. Durham.
Clinical Surgery—Mr. Forster, Mr. Bryant, Mr. Durham, & Mr. Howse.
Practical Surgery—Mr. Davies-Colley.
Clinical Lectures on Midwifery and Diseases of Women—Dr. Braxton Hicks.
Morbid Anatomy—Dr. Hilton Fagge and Dr. Goodhart.
Cutaneous Diseases—Dr. F. Taylor.
Anatomy (Descriptive and Surgical)—Mr. Howse and Mr. Davies-Colley.
Practical Anatomy—Mr. Clement Lucas, Mr. Golding-Bird, and Mr. Jacobson.
Physiology and General Anatomy—Dr. Pavy and Dr. Pye-Smith.
Practical Physiology—Dr. Pye-Smith.
Chemistry—Dr. Debus and Dr. Stevenson.
Experimental Philosophy—Mr. A. W. Reinold.
Practical Pharmacy—Instruction will be given in the Hospital Dispensary.

Clinical Lectures in Medicine, Surgery, and Midwifery, weekly.

Special Classes are held in the Hospital for Students preparing for the Examinations of the University of London and of the College of Surgeons.

The Museum of Anatomy, Pathology, and Comparative Anatomy (Curator, Dr. Fagge), contains 11,000 Specimens, 4,500 Drawings and Diagrams, an unique collection of Anatomical Models, and a series of 600 Models of Skin Diseases.

Appointments.—The House-Surgeons and House-Physicians, the Obstetric Residents, Clinical Assistants and Dressers, are selected from the Students, according to merit and without payment. There are also a large number of Junior Appointments, every part of the Hospital practice being systematically employed for instruction.

Prizes.—Two Entrance Scholarships, of £60 and £30, for proficiency in Classics, Mathematics, Modern Languages, Botany, Physics, and Chemistry. Six Scholarships, varying in value from £10 to £50 each, for general proficiency in Medical Study. The Treasurer's Gold Medal in Medicine; the Treasurer's Gold Medal in Surgery; the Gurney Hoare Prize of £25, for Clinical Study; the Sands Cox Scholarship of £15 per annum for three years, for Physiology and Physics; the Michael Harris Prize of £10, for Anatomy.

Fees.—First year, £40; second year, £40; third year, £30; or £105, in one sum on entrance, or in two moities, at the commencement of the first Winter and of the following Summer Session.

Several of the Lecturers have vacancies for Resident Private Pupils.

For further information, apply to the Dean, Dr. F. Taylor, or the Medical Secretary, Mr. Stocker.

Guy's Hospital, July, 1876.

ADDRESS IN PUBLIC MEDICINE.

By Alfred Carpenter, M.D., C.S.S.Camb.

A PARLIAMENTARY leader has spread far and wide the proposition *Salus populi suprema lex.* We are bound to believe that, when he uttered that sentiment, he honestly gave adhesion to the principle involved in it. Nay, the harassing legislation which a belief in its correctness helped to promote, has assisted to bring about the ebb-tide in the promotion of sanitary work which we are now witnessing. It may be thought that a proposition which has become a proverb, cannot be accepted as an axiom; the epitome of abridged wisdom which is wrapped up in its meaning being lost sight of. Such is the proposition to which the then Prime Minister gave utterance nearly three years ago, and which should be the watchword of the Health Department of this Association. The questions which are involved in the proposition are manifold, and their prosecution by the members of the medical profession has produced a greater number of enemies than it has brought friends.

Ebb-tide in sanitary work, however, is not to be wondered at. Terence wrote in ancient times:—

> "Obsequium amicos, veritas odium parit;"

and, as in times of old, so it is now, obsequiousness has no place in the performance of duty, and as a natural consequence its prosecution promotes opposition. It is my present purpose to show why opposition is attended with so much apparent success, to point out simple lines of progress, and propound a theory as a basis for continued exertion.

It is scarcely more than forty years since the first national platform was established upon which satisfactory observations could be made, and successful operations carried on in the cause of preventive medicine. The statistics which have been prepared by William Farr have been true pioneers of sanitary work. I would by no means decry the observations made by the old sanitarians. Howard and Pringle, Harvey and Jenner, with many other older workmen, are worthy of the highest regard by those who value the work in which we are engaged, and who think prevention of greater national importance than cure. If it had not been for the work of these eminent men, followed as it was by that of the enlightened politicians who framed and passed the Factory Act of 1833, and the Registration Act of 1834, William Farr's records would not now be matters of history, and we might still be groping in the dark as to the natural laws which regulate the health of the people, and be theorising as to the causation of disease, instead of calling upon Parliament to legislate for its prevention. The facts which have been brought to light by Farr's tables, the enormous mortality which has been shown to exist in defined districts, among defined classes of persons, and at particular epochs in their lives, together with the philosophical and suggestive papers which have been prepared by, or at the suggestion of, one who deserves as much of his country as any living man—I mean John Simon—have led to a flood of legislative measures, sometimes contradictory, passed in paroxysms; too often spasmodic in their character and unsatisfactory in their working; culminating at last in the enactment of a measure, which made the appointment of medical officers of health compulsory upon all local sanitary authorities. This measure has laid a foundation which enables us to apply particular observations to defined localities all over the country. The compulsory appointment of those medical officers was preceded by a permissive stage—permissive, first, in the application of sanitary work to a particular district—permissive, in the way in which that work should be applied, but at the same time accompanied by the stern resolves of the courts of law that, in applying those works and bringing them into practice, the rights of individuals should be respected. The antagonism between the *suprema lex* and the liberty of the subject; the opposition between *suprema populi* and the rights of property, continued to throw serious impediments in the way of sanitary progress, because the truths of sanitary science were few, whilst the *ipse dixits* of its professors, both medical and engineering, were numerous and contradictory. Especially has this been the case with the comparatively new profession of sanitary engineers, a profession which has sprung up to execute the works which sanitary science has called for; the members of which profession, in a large number of instances, were ignorant of natural science. Is it to be wondered at that Parliament in its wisdom passed permissive measures? Is it not a natural thing that those who had faith in the truth of their dogmata should ask for a trial of the principles they wished to be carried into practice, before making it compulsory on local authorities to entertain them? Was it not natural that those who desired healthy and satisfactory progress should prefer to see the suggested enactments in operation, and that they would wish to have an opportunity of studying their effects, before committing the legislature to a course of action which would have to be retraced if it happened to be projected on wrong lines?

Hence the value of permissive measures; the promoters of antagonistic schemes for the improvement of the health of the people have had a fair field: the principles upon which these schemes are based may have been correct, but unfortunately the advice of the medical expert has been but too often only half acted upon. The principles which govern the application of sanitary law have been only half understood by those who have had to carry them into practice, and have been only half applied. Medical men are not acquainted with the first principles of engineering work. To engineers has been most naturally entrusted the duty of devising and carrying out the works which were required for the removal of the causes of the disease, with the too frequent result of partial failure in effect, because sanitary law or a study of biology have not been the guiding stars of the engineer; whilst the medical adviser, being totally ignorant of the requirements of the former, has unwittingly passed over serious defects in the proposed schemes. The lesson which has been learnt is, that medical officers of health must know something of the first principles of sanitary engineering, so that they may be able to detect any grave defects in the works which a local authority may determine as requisite to be carried out in a given district. Such first principles must be part of the education of everyone, so far as they are connected with drainage, water-supply, and building construction.

Registration of the causes of disease tells us in conclusive figures that disease is irregular in its incidence; that it coincides in its incidence with certain social conditions; that certain forms of disease decrease or increase as those social conditions alter for the better or for the worse. The study of the statistics of a given locality is a mariner's compass to the student in prevention; whilst the rise and fall of certain forms of disease in that locality constitutes a barometer whose daily readings point out to the pilot the course which he should steer, and advises him of coming storms. It is only recently that every place has had its recognised pilot, whose duty it is to watch the indications afforded by registrations, and to advise the local authority accordingly. The indications are, however, not afforded to that officer at the most important and essential time, viz., at the very onset of epidemic or infectious disease. Registration of death is not in itself sufficient for the welfare of the state. The only information which a medical officer of health receives officially at present is that disease of an infectious character has been fatal in a given place some time previously. This information is conveyed to him days or even weeks after the event, and he finds, on inquiry, that the *materies morbi* has already been spread far and wide, that the contagia which have been produced by that case have been passed into the public sewer, the nearest water-course, or other receptacle for human excreta, and, as a consequence, have most likely multiplied indefinitely. It is also probable that many cases of the same kind occurred before one was fatal, and that no efficient steps were taken to localise or circumscribe the effects of the disease in that locality. It is more than probable that if the proper officer could have had information of the first appearance of that disease in the locality, the general distribution of its contagious particles would have been prevented, and the people saved some of the consequences of that distribution. A natural sequence to the registration of death is the registration of these forms of disease, for the repression of which a sanitary organisation is by law established. That registration will be effected in due course. It is a coming wave of legislation, waiting for the time when the natural history of those diseases which it is intended to encounter is more fully understood by the public, and more perfect knowledge obtained by ourselves as to the way in which preventive measures are to be used. We must be agreed among ourselves as to the proper steering course before we can have sufficient influence with the legislature to procure the enactment of a satisfactory measure. We must be agreed as to the class of disease which should be registered, and agreed also as to the persons who should give information to the registrar. I cannot support the opinion that it is our duty, as a profession, to give information on this point. A medical man, or, indeed, any other person, is out of place in undertaking a duty which may follow upon, but which is not a part of, the work he is asked to perform by his employer, especially if that work appear to be to the detriment of the latter. It would be morally wrong for a medical adviser to conceal the nature of a given case, if of an infectious character, from the knowledge of his employer, or the responsible head of the establishment in which his employer resides; but, the medical man having communicated that knowledge to him, the latter should be the party to give the information to the State, and be responsible to the local authority if he withheld it. The members of our profession cannot claim the protection of privilege in any case. If called upon, they would be obliged to convict the employer of neglect, if the latter failed to comply with the requirements of the law, if such should be enacted. The employer, or the person responsible for his welfare, should give notice, just as at present the owner of cattle is bound to send information to the inspector that disease of a certain kind exists on his farm. It was felt, when the Contagious Diseases Act was passed, that to call upon veterinary surgeons to give the required information would defeat the object of the Act. It would no less defeat the object in the case of human beings, if medical men were to be called upon to forward the information to the local authority; there would be an immediate premium on the employment of unregistered persons, and an effort made to suppress the discovery; and unless medical officers of health are to be entirely restricted from private professional work, it is quite impossible for such an enactment to work satisfactorily to the State, whilst, under any condition, it would be unjust to the private practitioner.

The progress which has been made in recent years in the repression of disease is marvellously great. The compulsory measures which are already on the statute book are extensive. The various factory acts, nuisance removal acts, registration, vaccination, and adulteration of food acts, acts for regulation of lodging-houses, of water-supply, and numerous other fetters which are placed upon disease production, both afloat and ashore, are very galling to a large portion of those affected by them; they are restive under the yoke, and will not understand the reason why those acts have been enacted. As a consequence, the unwritten and unexpressed object of our legislators is to prevent the rigid application of the laws of health to their own particular locality. It is true that many among them are energetic, but many too frequently follow the shadow rather than the substance, they raise some question on some trivial side-issue, and make a strain at a gnat, but on great questions which affect themselves they swallow the camel with the greatest ease. No better illustration of the truth of this proposition could be afforded than the action of a portion of those persons who have been recently agitating for a so-called Vivisection Bill. Some of these persons are per mitting cruelty of the most excruciating character to be daily inflicted on their flocks and herds. They allow castration and other painful operations to be performed in the most painful manner on all classes of animals on their estates. They allow the cottages of their poor tenants to continue in a condition in which morality and chastity are impossibilities; whilst drunkenness, wife-beating, and child-murder are the natural sequences to such states of habitation. These things go on every day before their eyes. They have the power to prevent them, but they do not; yet they do raise their voices in shrill clamour against comparatively humane actions which they do not understand, which have for their objects the diminution of suffering in the future, and an elucidation of the truths of physiological and pathological science. The truths of those sciences are so telling against certain forms of quackery and delusion, that it is not surprising to find the supporters of quackery among the promoters of the Vivisection Bill. They would stop the study of physiology if they could, for it deals death blows at the —pathys and —isms in which they delight.

I would not, however, have it considered that we are in favour of the cruelty which is said to be practised by scientific students in demonstrating physiological facts. When I was myself a student, I was never cognisant of such, and I believe that the statements are gross libels on our profession—libels which are quite unworthy of any Government to have countenanced, and are an indication of a desire on the part of some of the ruling powers to put a slight upon science, and especially upon that profession which includes among its members a large portion of the searchers after the hidden truths of nature.

An idea is now present in the minds of the ruling powers that they do not intend to be doctor-ridden. They have done a great piece of satisfactory work; they have made the appointment of Medical Officers of Health compulsory. Some local authorities have even conscientiously performed their duty, and have appointed efficient officials.

The medical officers so appointed have zealously set to work to find out the sanitary defects which exist in their district, and have made elaborate reports regarding the same. Many are astonished to find that, although appointed to do certain work and to make certain suggestions for action, no action is taken, and things remain much as they were before the appointment was made. There is nothing very extraordinary in this. It is the rule in every-day life. The custom of the unit is necessarily the custom of the aggregate of units; and the local authority does that as a body, which the majority of individuals comprising it do in their daily life. It is the same result which naturally follows when a medical man offers his gratuitous advice to his wealthy patient at the wrong moment. The country is now passing through a phase of this kind; honest and conscientious medical officers of health are bringing down upon themselves a shower of indignant remonstrances, of widespread abuse and energetic opposition from local John Bulls, who do not recognise the fact that the State is suffering from mischiefs which can be removed if proper measures be taken for their removal. The reports of medical officers of health lie on the table, and very little concerted action is taken for the removal of those causes of disease which have been so ably and clearly pointed out. The patient is saying pretty plainly that he does not intend to rigidly obey the laws of health, or to be doctor-ridden, and until some wave of epidemic disease arises, and compels him to reconsider his determination, he will not alter his course, or take a different line of action; he may then instruct the sanitary engineer to carry out costly works which remove the most flagrant nuisance, but when carried out they often do not effect all the objects intended, because some first principle of sanitary law is altogether overlooked.

These results, though not due to defects in sanitary science so much as to construction of works, are leading the public to inquire for themselves and to criticise our actions. Fortunately for science, physiology is taught in some of our elementary schools, whilst honours are taken at our universities in natural science by men who do not intend to enter the medical profession. The youth of both sexes are learning more and more the laws of Nature, and imbibing the first principles of physics. A portion of the public believe that it is the duty of the physician to give a reason for the line of treatment he is pursuing; they will not be satisfied with an evasive answer, whilst the more sensible portion will not be led astray by a false one. Our explanations must be either strictly correct, or so framed as to apply to a possible hypothesis, and not be contrary to the laws of natural science. To the medical profession the country owes in a great measure the knowledge which has been obtained of the laws which apply to the prevention of disease. As a profession we must continue in advance of laymen, and we must not allow the idea to gain ground that prevention and cure are different studies, and may be entirely separated from each other. It may be even that one will supersede the other and become the more noble study, but to give currency to the proposal that medical men should not be called upon to consider the means to be used for the prevention of disease, and that they may ignore the operations of the engineer, would be suicidal. We must know how to prevent the disease if we would retain the confidence of the public. If we are properly acquainted with the best principles of prevention as well as of cure, our objectors will not be long in finding out that they had much better be doctor-ridden, as they style it, than put their trust in delusions. At the same time it is our duty to advise, not to dictate; to recommend, not to command; and to support our recommendations by arguments based on sound science. If the doctor be unskilful, addicted to dogmatise, and to advance opinions which are not founded upon scientific truths, he is doing serious harm, and helping to promote those forms of quackery which are so rife among the idle, the self-willed, and the half-educated ignoramus of society. We require a clear insight into the conditions which give rise to disease, to reduce the principles of preventive medicine to the plainest lines, and to bring it into formula which may be at once assented to; perspicuity being the basis of all true knowledge in every branch of study.

I will set out what I believe to be some of these bases. The first principle of sanitary work is *motion.* Any plan which entails stagnation as a part of its scheme must have the cause for that stagnation very clearly expressed, and a sound reason given for it, or the scheme is bad in design, and not calculated to effect the object for which it is proposed. This is a canon law with reference to the first great purpose of the sanitary officer. From the moment of excretion until it is utilised, motion of the excreta is the first sanitary law. If the excreta of carnivorous animals be kept moving, those combinations which produce epidemic disease are not forthcoming. For this purpose sewers are required in crowded localities. They are the necessary evils which follow upon the aggregation of individuals into crowded communities, though they are quite out of place in the village and the isolated mansion. Any sewer so constituted as to allow stagnation of any of its contents in any part of its course is wrongly made. If arrangements be introduced which necessarily produce stagnation in the air, if only for a few feet of house-drain, a manufactory or vineyard is allowed to exist in which contagious particles may vegetate, and may be the starting point of a fresh epidemic; any trap on a sewer which is not accompanied by a corresponding ventilator may become a trap to catch men. Any sewer so constructed as to allow of deposit of solid matter, or which allows sewage to stagnate in any part of its course, is in a similar condition. Sewers must contain a current of sewage constantly passing down, with a corresponding current of air always passing one way or the other, if they are to be kept free from the power of manufacturing mischief. Ventilation must be free and absolute, ingress being allowed as well as egress, in a way which cannot be counteracted. For every house in connection with a public sewer there should be at least two free openings provided in the house-drain, an inlet as well as an outlet. If this arrangement be carried out, and the opening contrived so as to effect the object in view, and not for the purpose of

b

defeating it, the natural forces will more effectually ventilate the sewers than any artificial aids. The diffusion of gases, the tension of vapour, the differences of temperature, in the sewer as compared with the outer air, the constant movement of external air, together with the movement of sewage in the sewer, will suffice to produce a free ventilation at all times. If this be done, no contagium particle will have a chance of reproduction in the contents of sewers, and no sewer gas will be discharged which will convey elements of mischief.

Deposit must not be allowed to take place; sewers must flush clean. The engineer who constructs sewers so that a deposit is probable in the invert of the arch has failed to effect the object for which he was engaged, and has erected an elongated cesspool. A sewer must flush clean under all circumstances. If sewage be always moving in the sewer there will not be time for deposit, there will not be time for those changes to take place upon which the production of contagia depend, so that motion prevents evil. Sewage must continue in motion and pass on to its destination. There is another point worthy of mention which is too often forgotten—fresh sewage does not smell. If a sewer stink, it is defective in its workmanship somewhere. It is not sanitary science which is at fault, but engineering work. Sewers which give out unsavoury odours ought not to be accepted. They are defective either in their ventilation or in their levels; they are either wrongly designed or badly executed; and the engineer should be called upon to rectify the mistake.

Sewage cannot be retained in a sewer or anywhere else for more than twenty-four hours without producing a chance of evil; long before that time has elapsed it ought to be on its way to be utilised. The moment utilisation of sewage has properly commenced, from that moment the evils which might result from sewage recede into the far distance, and it becomes ineffective as a focus of infection. At present, nineteen-twentieths of the sewage produced by the thirty-two millions of Great Britain is cast into the sea, or allowed to decompose after it has set up an immense amount of disease. Some of it becomes food for fishes, but the major portion is lost for ever by its reduction to its original elements.

(*To be continued.*)

◆

ON THE TREATMENT OF INFANTILE CONGENITAL CLUB-FOOT. (*a*)

By W. J. Little, M. D.

I propose to sketch the earlier and more recent experiences in the treatment of Infantile Congenital Club-foot, since the introduction of subcutaneous tenotomy by Stromeyer, and especially to point out the practicability and the advantages of conducting the mechanical part of the treatment from beginning to end with padded metal splints instead of more elaborate appliances.

As a stranger to Edinburgh I am ignorant, as far as personal observation is concerned, of the state of the treatment here of this important, and, if neglected, serious deformity. I am more than satisfied by having Edinburgh as the theatre of my remarks, from the knowledge that nowhere better than in this University can a full investigation of a subject be secured or any practical good to humanity be evolved from it. Whatever degree of perfection the treatment of club-foot may here have reached, I have good reason for saying that in many parts of the United Kingdom from which members of the British Medical Association here assembled have come, there is much to be desired before it can be considered that prompt and efficient treatment of congenital club-foot is the rule of surgical practice.

If I had had the honour of presenting myself before you forty years ago, I might have heralded here, as I did in London two years later, the discovery of true subcutaneous division of tendons by Stromeyer, (*a*) an event which took place four years before, and the fact that several adolescents and adults have been cured of different forms of contracture by that subsequently distinguished surgeon. An analysis of the work of Stromeyer, published in 1838 (Beiträge zur operativen Orthopædik, Hanover), shows that the average age of his operated patients, including both congenital cases and non-congenital ones, was eighteen and a-half years, that of Duval "Traité Pratique du Pied-bot," 1839, was fifteen and a-half years, my "Treatise on Club-foot and Analogous Distortions: London, 1839," exhibits an average of seventeen and a-half years, whilst Dieffenbach's book "Die Durchschneidung der Sehnen, Berlin, 1841," that is, three years later than Stromeyer, shows an average of thirteen years of age. It was natural during the infancy of the division of tendons that parents and adults should have been more willing to present themselves for relief by an operation imagined to be a serious one, than to bring infants and children for that purpose.

As early as 1836, in my Inaugural Dissertation at Berlin, "Symbolæ ad Talipedum Varum Cognoscendum," following in this respect the opinion of the physiologist Rudolphi, I pointed out the dependence of varus upon contraction of the anterior and posterior tibial muscles, as well as upon contraction of the gastrocnemii; and in May, 1837 (see "Treatise on Club-foot," &c., p. 212), added division of anterior and posterior tibial tendons as a necessary preliminary proceeding in well marked congenital varus. At this date I also severed the flexor longus pollicis, the extensor proprius pollicis, peronei, and the ham-strings in other forms of contraction. Stromeyer, who had previously considered the inversion of the foot in congenital varus to be due to the action of the gastrocnemii only, objected to division of the tibial muscles. Twice only did he divide the posterior tibial in congenital varus as an experiment. (*b*) Stromeyer has since directed his mind to wider fields of surgery. I believe that if he had continued to labour at distortions, he would long ere this have endorsed my opinion and practice as to this matter. Dieffenbach followed the teaching of Stromeyer, and appears from his work above quoted to have only once severed the posterior tibial tendon. The case was that of a boy twelve and a-half years of age. German and French surgeons have usually followed the example of Stromeyer and Dieffenbach.

At the same time I showed, as others had previously done, that malformation of the bones of the ankle and tarsus was not the cause of the distortion. (See on the "Nature of Club-foot and Analagous Distortions and their Treatment, with or without Surgical Operation, 1839." *Introduction*, p. xxix.) I agreed with Scarpa with respect to the anatomical malposition of the bones, and the conclusion at which he arrived, viz.—"That of the entire tarsal bones, the astragalus had suffered the smallest degree of displacement, which alone proved the possibility of curing infantile varus.' I showed that in every instance of infantile or adult varus examined anatomically, however great may have been the state of extension and adduction of the foot, some portion of each of the three articular surfaces of the trochlea of the astragalus was in contact with an equal proportion of the three articular surfaces presented by the tibia and fibula in the ankle-joint, and that the essential peculiar characteristic of varus was the dragging inwardly of the navicular and of the remaining tarsal bones away from the astragalus and os calcis, by the contracted anterior and posterior tibial muscles, aided by the long flexor of the great toe. By

(*a*) An extempore address delivered at Edinburgh, together with additional observations.

(*a*) Delpech "L'Orthomorphie," vol. ii. p. 330, proposed excellent rules for dividing tendons without exposing them; but in the only case which he operated he transfixed the limb with a scalpel, and made a wound one inch in length on each side of the tendon, and afterwards divided it by means of a convex-edged bistoury. See "Little on Club-foot, 1839," Introduction p. liv. This was not subcutaneous surgery.

(*b*) See "Stromeyer Bieträge," 1838, p. 80, and also 10 of this paper.

this time all the requisite knowledge of the morbid anatomy of congenital club-foot, which was essential for the cure of even severe forms of it, had been obtained.

The subcutaneous division of the posterior and anterior tibial tendons previously confined to patients above the age of two and a-half and three years, was extended by me to young infants before 1842. (See Lectures in the *Lancet* on "Deformities of the Human Frame" of that date, reprinted by me under the title of a "Treatise on Deformities of the Human Frame," with additions (known by insertion within brackets) in 1853, pp. 283, 292, and 297). Previously to 1839, I had divided the posterior tibial subcutaneously in children above the age of two or three, and in adults, by passing the knife beneath the tendon above the malleolus from behind forwards, where it could be *seen* and felt, and be severed with comparative facility. In stout fat infants I was then accustomed to divide the posterior tibial by means of a departure from subcutaneous division of tendons, by making a longitudinal wound three-quarters to an inch in length over the tendon above and behind the malleolus. But a death about this time through phlegmonous erysipelas occurring in a stout adult female in whom I had severed the peronei by open wound, led me to a final abandonment of this unfortunate departure from subcutaneous tenotomy.

Subsequently (*British and Foreign Medical Review*, 1844, vol. xxi.), I introduced the plan of dividing subcutaneously this tendon from before backwards above the malleolus, since which time the operation even in stout infants has been rendered comparatively easy in practised hands, and acknowledged by many to be a necessary one in severe infantile congenital varus. When first introduced this division was effected *à deux temps*, using two knives, one of which was blunt-pointed. Mr. Gowlland, in 1853, performed it in a single proceeding, using only one knife.

Gradually these improved methods have made their way and are now commonly employed. Previously to 1840, division of plantar tissues, although practised by Stromeyer, Dieffenbach, and myself, was more prominently recommended by Mr. Martin Coates, in a valuable pamphlet published at that date.

By this time also the application of tenotomy to very young children had been encouraged by the example of Dieffenbach (four days old), 1841, Evory Kennedy, of Dublin (four weeks old), 1840, and of myself. In my lectures, printed in 1843-4, I was able to state that I was accustomed to operate on children as early as the age of six or eight weeks, when satisfied that the case was irremediable without it. (a)

From this period to the present day there has been a progressive disposition to operate at the earliest possible period—on the day of birth (L. S. Little), at two days old (as by myself), during the first week or month, in suitable cases. No one unaccustomed to treat these cases at the earliest age can realise the enormously increased facilities of cure it presents. To complete this brief historical sketch of the principles successively laid down more than a generation ago for the application of subcutaneous division of tendons, combined with the mechanical treatment, to the cure of congenital club-foot, I will add that in 1839 ("On the Treatment of Club-foot and Analogous Distortions, with and without Surgical Operation," pp. 209), I published the particulars of restoration to form and function of as severe a degree of congenital club-foot, in a young man, aged 17, who was operated on in 1837, as has ever been published before or since, to my knowledge, in any country. In that case division of anterior and posterior tibial tendons and achillis tendon was effected. (a) Many years before, Continental surgeons who had devoted themselves to the cure of deformities by instruments only, had laid stress on the importance of endeavouring to correct the inward twist of the foot before attempting to bring down the heel. In 1837 I applied this principle to the severe curable forms of adult varus, by devoting all attention to removal of the inward twist by means of a straight wooden splint, furnished with a steel spring, bandaged on the outside of the leg, until the foot had acquired a position in a straight line with the leg, and, indeed, until it had assumed a valgoid position. Afterwards depression of the heel was effected, and the foot made to rest with the entire sole on the ground. Up to this time Continental surgeons in general, as far as can be judged from their writings, had not attempted to cure severe cases such as that represented, Case xxiii., p. 209, "Little, Treatise on Club-foot and Analogous Distortions." The cases previously operated abroad were mostly cases of non-congenital varus, and the slighter congenital ones. This result was the effect of their insufficient original investigation of the morbid anatomy of congenital varus, and of their belief, following the opinions of Scarpa, Stromeyer, Delpech, and Cruveilhier, in the dependence of congenital varus on primary deformity of the bones, and consequent failure to note the influence exercised in the production of the deformity by the posterior tibial muscle.

In some cases the comparative difficulty of severing the posterior tibial led to disregard of this operation.

The prominent superficial situation of the achillis tendon sufficiently accounts for the shortening of this tendon having early, and at first, exclusively attracted the notice of the majority of surgeons, and often of their patients (see "Little on Club-foot and Analogous Distortions," 1839, p. 79). For similar reasons the anterior tibial soon attracted notice, and was subjected to division. Next came the turn of the long flexor of the great toe, and of the plantar fascia.

No improvements on these principles of treatment have been effected since that period. Individual surgeons have acquired technical skill, or have introduced modifications in apparatus. Evidence in proof of this assertion is afforded by the cases and illustrations appended to my work of 1839, already quoted.

It was then with justice triumphantly felt that as regards congenital club-foot, a success never before reached in the history of orthopædic surgery had been obtained. *A fortiori* how much more readily and certainly might not in future infantile congenital club-foot be cured! Some tinge of enthusiasm may at that time have been pardonable.

At the periods in question, therefore, *i.e.*, in 1839, and more emphatically in 1842, it was shown, by example and precept, that in order to rectify the form and position of varus or congenital club-foot, whether treated with or without surgical operation, the treatment should be divided into two stages:—

1. That in which the inward twisting of the foot should, in the first instance, be rectified, and the distortion be thus converted from a compound distortion to a more simple one, *i.e.*, from varus to equinus. (a)

(a) Mr. Wm. Adams' "Club-foot: its Causes, Pathology, and Treatment. London, 1873," has erred in having quoted a passage written by me in my Lectures in the *Lancet*, 1843-4, and reprinted by me in a "Treatise on Deformities of the Human Frame," 1853, p. 284, on the subject of the time when operative interference is desirable, and against early operation, omitting, at the same time, to make any quotations from the same lecture in favour of early operation. Thus, at p. 283, when advising "that in every case, the treatment of which can be commenced previously to the age of six months, the case should be attempted by the application of mechanical means," I added a note in 1853, "the exceptions are like fig. 104, p. 265, which, from the outset, at the age of two or three months, require operation." Again, at p. 291, I said, "In this institution I frequently recommend tenotomy in very young infants, sometimes so early as the age of six or eight weeks," and I added a note that Dr. E. Kennedy, of Dublin, previously to 1840, operated on an infant four weeks old. Mr. Adams, in 1873 (*opus cit.*), has also passed over without notice my observations in favour of early operation when unmistakably indicated, contained in "Holmes's System of Surgery, Article Orthopædic Surgery," first edition, 1862, vol. iii., p. 568, contained also in Holmes's second edition. If an author's opinion be cited and criticised, his latest published recommendations should be quoted.

(a) See "Treatise on the Treatment of Club-foot and Analogous Distortions, with and without Surgical Operation," 1839, p. 209.

(b) See "Little on Club-foot and Analogous Distortions," London, 1839, Case xvi., p. 164. Remarks on it, p. 168. Also

2. That in which the straight looking but extended and still contracted foot *equinus* should, by the bringing down of the heel and by elevation of the fore part of the foot, become capable of being planted evenly on the sole, and that if the varus was sufficiently severe to require division of the anterior and posterior tibial tendons, this operation and conversion of the varus into equinus should precede division of the tendo-achillis and the bringing down of the heel.' (a)

It was, however, customary for several years after this date to disregard, especially in very young subjects, the subdivision of the operation into two stages, as above described. This course was followed with the view of saving the feelings of parents by compressing two operations into one, especially at a time when anæsthetics had not been discovered.

The positive evils which, it will presently be shown, may arise through simultaneous division of the tibiales and achillis-tendons, or from the division of the achillis only, previously to the correction of the inward tendency of the foot had not been discovered.

Those surgeons who have no experience of the curability of the less severe forms of varus without any operation, and whose practice it is to resort to tenotomy in every case, appear not to be aware that by mechanical treatment in many cases the inward inclination can be removed by use of an outside splint, the foot, as I have said, being then converted from a varus form to that of equinus. When this conversion has been effected, and the necessity of severing the anterior and posterior tibials has been removed, the question remains whether or not it be necessary to sever the tendo-achillis. Sometimes even this operation is not necessary. More commonly it is needed. Considerations such as are suggested by these facts have always induced me to discountenance early operation except in well marked or severe grades, of which the surgeon experienced in treatment of varus can easily decide; and to encourage the surgeon practising away from the large centres of population to try what he can accomplish by simple mechanical means. If in a few weeks he succeeds by mechanical means in removing the inward inclination he may then have to effect the division of the tendo-achillis, which is a simpler operation, or even complete the cure without operation.

By being able to substitute a simpler operation for a more complicated one in suitable cases, the patient becomes in every way a gainer. Unnecessary division of tendons leads to diminished symmetry and strength of limb, whilst, on the other hand, a necessary division of tendons, by restoring the functions of the contracted joints, favours the restoration of form and movement.

Enough has been here said to warn against the practice of immediately operating in every case of infant congenital varus which presents itself, and in favour of circumspect, gentle, earnest efforts with mechanical appliances and manipulations in slight cases, or those in which doubt exists as to the absolute need of operation.

A few weeks employed immediately after birth in endeavouring to remedy at least the inversion, will involve no risk of aggravation of distortion, as is the case when any beneficial treatment is purposely postponed to a later period. The surgeon has to take care that the case shall be cured before the age at which a sound child usually walks.

In 1842 I was justified in the sanguine statement that within the lapse of another generation persons labouring under congenital club-foot would not, as was then too commonly the case, be seen walking in our streets. The hopes of a generation ago have not been entirely realised. Moreover, many incompletely restored cases are common in public places, in hospitals, and in our consulting-rooms. It is a fact that cases frequently present themselves of children and youths who have been operated in one, two, or even three hospitals, or by different private and orthopædic surgeons, and are still far from restoration, indeed some of them are in a worse position than if they had never been touched, because the operated tendons have been unduly lengthened, secondary deformities have been produced, the retracted bellies of the gastrocnemii, forming, for example, a small wasted mass high up towards the ham, the nutrition of the bones of the leg and of its remaining structures generally much reduced, the temperature ill-maintained, troublesome chilblains adding to the patient's annoyance during winter, the motion in the ankle-joint often less, and the contraction of the plantar tissues greater than when the individual was born (a).

Lectures in the *Lancet*, 1843-4, reprinted "Deformities of the Human Frame," 1853, p. 285, 295, 303.

(a) Stromeyer was the first (in 1836) who divided the posterior tibial. His proceeding was by a preliminary incision three-quarters of an inch or one and a-half inches in length. The cases in which he divided this tendon were two non-congenital cases, aged respectively eleven and twenty-eight, and two congenital ones, aged respectively four and five years. In respect of these cases he departed from his own subcutaneous method. These operations were performed between August 1, 1834, and February, 1837. He did not afterwards repeat division of the posterior tibial. The following were his reasons for the abandonment of this operation ("Beiträge," p. 81):—"The contemplation of these cases appears to indicate that section of the posterior tibial exercises no decided influence in the restoration of the form and function of club-foot; yet I will not deny that this subject requires further investigation." As regards the history of this operation, it may interest to state that in 1836, whilst in Berlin, I was engaged in investigations of the morbid anatomy and treatment of club-foot, I informed Stromeyer, by letter, of my conviction that congenital *varus* depended upon contraction of the anterior and posterior tibials, as well as upon the tendo-achillis. Stromeyer's reply was to the effect that the posterior tibials had nothing to do with the production of varus, and dissuaded me from division of it. I was not aware until the appearance of his work that he had already performed the operation several times. In the work ("Beiträge," op. cit., p. 29) he gives full reasons for his conduct. It is worthy of notice, that acting without knowledge of Stromeyer's previous practice, I kept to the subcutaneous method in the five cases in which I divided the posterior tibial between November, 1837, and March, 1839, related in "Little on Club-foot," &c., 1839, Cases xviii., xxiii., xxiv., xxviii. The youngest of these cases was two and a-half years. The mode of operation was that described in this address, p. 6. Many others were afterwards operated on by me in the same way. The subcutaneous method, as regards this tendon, was very simple, and not difficult when the tension of it was distinct to the eye and touch in their subjects. It was different with young infants, in whom, by the first month after birth, and some times at an earlier age, the ankle was surrounded by so much adipose tissue that the posterior tibial was in them never visible and never distinctly felt until after much experience had been acquired. A striking difficulty arose when wishing to apply to infants that subcutaneous section of the posterior tibial which I had proved to be so useful in older subjects. Therefore, after 1839, I ventured upon a departure from the subcutaneous method, and exposed the posterior tibial by a three-quarter inch incision, and divided it many times, as Stromeyer had done, with impunity. I abandoned it for the reasons already referred to in this address, and between 1836 and 1843 laboured at the discovery of a secure method of reaching the tendon subcutaneously, even in very fat children, which was effected, and which is fully detailed, "Little: Treatise on Deformities," &c., 1853, p. 297.

(a) I should fail in my duty to the profession and to the public, if I did not unhesitatingly here state that many of the most able surgeons, as well in the metropolis as in the provinces, have inflicted much injury by heedless tenotomy, that is through having undertaken the treatment of these cases without sufficient previous study of the subject—through insufficient acquaintance with the mechanical aids requisite, or disregard of the teachings of their predecessors, as to the value of manipulations, and the mischief resulting from keeping a part too long *secured* in an apparatus. I will adduce a case in point: A parent lately brought to me a child four years old, who had originally been affected with congenital varus of average severity. The family surgeon had fruitlessly cut the tendo-achillis, and used a so-called Scarpa shoe. The distortion being unabated, and the child already walking in the position represented in fig. 1 of this paper, the family surgeon sent the patient, with a letter of introduction, to the surgeon of a metropolitan hospital, who admitted the case into his hospital, and, in addition to the re-division of the tendo-achillis, severed the anterior tibial, kept the patient three months in the hospital, and sent the child home wearing an apparatus similar to that previously employed by the family surgeon, with the foot apparently none the better when examined out of the apparatus. A few months more elapsed, the deformity and difficulty of walking becoming aggravated, the child was again sent to the metropolitan surgeon, who again took it into his hospital, repeated the opera-

It is possible that exceptional circumstances have led to my becoming consulted as to a larger number of incompletely cured, damaged, or neglected cases. But I am not singular in being placed in a position to observe that relapsed or imperfectly treated cases abound. Mr. Jackson and the rest of the staff at the National Orthopædic Hospital in Great Portland Street, London, can testify that nearly as many cases of the latter class present themselves as of young previously untouched infants. A friend of mine of long-standing, whose praiseworthy and successful efforts for many years to relieve the mischiefs caused by the unsuccessful treatment of congenital club-foot amongst the well-to-do members of the population, and more especially amongst the poor, justify my mentioning his name—Mr. Clowes, of Windermere, informs me that he continually sees cases lamentably indicative of want of skill in, or ill-luck attendant upon, treatment.

This side of the picture of the results of subcutaneous tenotomy after general employment of it for more than a generation is indeed a sorry one. The other side of the picture is, I rejoice to say, a bright one, and need not, therefore, so long detain us.

I am here to-day to ask you to consider with me for a few minutes whence comes the sorry side of the picture which, but for the bright side, would be a subject of sincere humiliation to us as a profession. It should in justice be stated that until the days of Stromeyer all was dark in the condition and prospects of everybody affected with well-marked congenital club-foot. Despite writings on the subject by Hippocrates, Scarpa, Delpech, and many others, only those cases of club-foot of the slightest grade, such as can now-a-days, with the improved knowledge at our disposal, be cured more easily without operation, had the smallest chance of being restored—they trudged on their way in the forlorn deformed state in which we occasionally meet some of the present generation, the great mass of congenital club-foot persons, estimated by me at probably one in 2,000 of all born in Western Europe, wearing heavy, clumsy irons, eking out scanty pleasure, if not positive pain, from their indifferent locomotion.

When we contemplate the perfection with which the worst forms of infantile congential club-foot are, under favourable conditions, remedied at the present day, we may console ourselves for some disappointments, and be reassured that the subcutaneous method of Stromeyer has conferred great blessings on humanity, has increased the usefulness of our profession, and given it an additional claim to the regard of society at large.

What are the causes of the failures or relapses from complete restoration which are met with in public practice, and among even our private patients?

From the number of cases of varus which present themselves in which treatment has been delayed until the infant was presumed to be old enough for operation, it would appear as if, since tenotomy has been in vogue, practitioners had given up as superfluous the common sense treatment by any domestic articles available for splint and bandage, to which their forefathers resorted. This has been one regrettable result of the prominence attached by many surgeons to treatment by operation. (a)

In the next rank I believe must be placed the omission to operate at a sufficiently early age those cases which appear undoubtedly to require its performance. So long ago as in 1839 and in 1842, as already stated, I endeavoured to lay down rules for determining what cases respectively could be remedied without operation or by its means, and recommended that cure should be accomplished before the age at which sound children usually walk. The fact that the majority of operated patients had been adults, and that section of tendo-achillis alone gave great relief, retarded the extension of tenotomy to other tendons by the profession at large, and tended more to operations on adults than on infants. Each succeeding year has increased the conviction that to restore the part to its proper form and movements as promptly as possibly, with or without operation, as the nature and severity of the case indicate, is the certain mode to obviate the tendency of the bones, ligaments, muscles, and fasciæ to become more and more shortened, wasted, deformed, and weakened, in proportion as the limb grows. If the practitioner considers the case to be a favourable one for mechanical treatment, and finds, after due attention to it, that adequate progress be not made, he should at once operate. Delay in the completion of effective restoration of form and movements *before* the age at which robust children usually walk is mischievous, but after that period every day's delay does manifold greater injury. The tegumentary structures, the muscles, tendons, fasciæ, and ligaments in all situations round the ankle, and those connecting the tarsal bones, metatarsus, and toes, situated on the contracted side of the member, become daily more shortened, and exhibit greater opposition to restoration, whilst the similar structures situated on the opposite side of the member become daily more elongated and weakened. In the less deformed cases the deeper structures, as well on the back and inside of the leg as on the sole, appear little concerned in the production of the distortion.

Every step made with a foot not capable of being placed evenly on the ground with so much of the entire sole as a sound person applies to it, occasions a certainty of aggravation of the deformity, and augmentation of the difficulty in obtaining perfect restoration.

(*To be continued.*)

Literature.

LECTURES ON SURGERY. (a)

Although Mr. Spence specially intends this work as a text-book for his class, still he is not without hope that it may also prove useful as a work of reference for practitioners. No doubt Mr. Spence's pupils will find it of great use in the study of surgery under their able teacher, but we doubt if the work will be much read by students who cannot enjoy at the same time the advantage of Mr. Spence's oral instruction. As a book for students it is not all that it might be. In some parts the description is poor to a degree, quite insufficient for preparing a student for an examination, unless, indeed, the examinations are very different in Scotland from what they are south of the Tweed. Perhaps, however, these bald places in the text are really filled up by reference to principle and detail in the lecture as given. Probably this is the case, for if each chapter represents the teaching of one lecture, we could not otherwise account for the shortness of certain of these

---

tion, ordered an apparatus, again leaving the mechanical treatment to his house-surgeons and dressers. After the second stay in the hospital—this time of four months' duration—the parents removed the child. The case was as bad as a case of neglected varus of four years old can be, with the aggravation of several large cicatrices above the insertion of the achillis tendon into the heel, two considerable (by comparison) scars over the insertion of anterior tibial tendon. The posterior tibial tendon did not appear to have been touched. By this paper I desire to show that such occurrences are not desirable or unavoidable. I do not exaggerate when I say that I have come across many scores of such cases with the same history. These are not cases of accidental failure of treatment, but cases in which all the principles of treatment, as laid down in this paper, and in many previous writings of my own and of other authors, have not been followed, and in which the surgeon has neither attended to the details of treatment himself, nor placed the management, after operation, in the hands of competent assistants. They are a discredit to surgery, and it is indisputable that no graver charge can be brought against special hospital (orthopædic) surgeons than that which might be brought against those general hospital surgeons who treat congenital varus in the manner I have instanced.

(a) The title of the author's first work published in this country shows that in 1839 he, at least, did not attach exclusive importance to division of tendons.

(a) "Lectures on Surgery." By James Spence, F.R.S.E., Surgeon to the Queen in Scotland. 1875. Second Edition. Edinburgh: A. and C. Black.

chapters. Lecture XVII., for instance, which is an introduction to the cancers, occupies but three pages.

The subjects of *inflammation* is hurried over and treated in anything but a masterly manner, whilst in the short account which is given of *pyæmia*, the only reference which we can find to the characteristic variations of the temperature is included in the terse remark, "The temperature is subject to great and sudden alterations." The pupil is told that "the typhoid nature of the symptoms renders them very analogous to those induced by certain annual poisons" (p. 131), but he is not informed what the diseases are for which pyæmia may be mistaken; nor is he, of course, told how the diseases differ. Again, in speaking of gangrene (p. 62), the author says that when the disease ceases to extend, "a line of demarcation is formed between the dead and living tissues." He does not explain what this line is, nor what it is due to; nor does he say that the line is chiselled out by nature at the expense of the *living* tissue. We do not think that it is sufficient to tell a student merely that there is a line of demarcation between the living and dead tissue. As regards the treatment of gangrene, the author teaches his students that they may give ammonia in extreme cases to stimulate the patient, but not in cases of urinary infiltration, for that "it tends to favour decomposition of the urine." We question the expediency of giving his pupils this caution.

We believe that the practitioner will derive great assistance by reference to the book before us, for if it be wanting in the theoretical part, it certainly does not fall short as regards the practical part of the teaching. The advice given to surgeons to open acute abscesses early and freely, not to keep on poulticing too long, and to let the incisions in the ligature of vessels, and in lithotomy, be free, shows that the surgeon is well aware of the fact that much of the operator's success will depend on attention given to comparatively small matters. He tells his pupils to make an early incision in case of whitlow and deep-seated abscesses in the neck and perinæum, rather than to wait for distinct fluctuation.

In the lecture on Syphilis we read: "I do not believe in two distinct poisons, though I consider that the poison may differ in degree rather than kind, and that the same poison may produce different forms of sores, owing to the susceptibility of the person or part affected, and other conditions." We read on the same page (120) that secondary and tertiary symptoms may follow on a soft sore. With these remarks we entirely agree. The soft sore, we are also told, heals most quickly after having been burnt with sulphuric acid; and that, as regards the hard chancre, "we require to be very active in our treatment. If we see the case early we must destroy the sore by potassa fusa." But if, when the slough has come away, we find the edges hard, we are told to work away again with our caustic. We are led to infer—indeed, we are told further on—that secondary symptoms will probably follow on a hard sore, "even though the primary hard chancre has healed rapidly." In these circumstances we would venture to ask Mr. Spence what good his painful meddling with the hard chancre has wrought? If the indurated sore appeared very shortly after impure contact, we might possibly do good by active treatment with caustics, but as a matter of fact it does not.

Lecture XXIII. is a most happily written chapter on *wounds*, and in it the student is cautioned, and, we think, advisedly, against being led away by the wondrous reports, especially those coming from abroad, of the "antiseptic treatment." The lecturer is right in saying that the antiseptic method, "as it is termed, is being pressed in some quarters to the exclusion of conditions, which I think equally, if not more important in the treatment of wounds and operations. . . . Some of the statements advanced in favour of the antiseptic system so ignore the success obtained by simple dressing and treatment of wounds, or assert such an amount of infallibility as to the curative powers of the special method, as to require notice." The statements, the author considers, arise from want of experience in, or misrepresentation of the simple method of treating wounds.

In the same cautious tone does the Professor speak of the somewhat modern system of treating fracture by the plaster-of-Paris bandage. He says that he thinks that when we possess well-tried, simple, and successful plans of treatment, we should be very chary in departing from them. "Novelty," he says, "is not always progress, and, unfortunately, many novelties in surgery at the present day seem to consist in departure from simplicity of treatment."

In referring to Esmarch's bloodless method, he remarks: "The principle, it will be seen, from what I have already said, was clearly enunciated by the late Sir Charles Bell, and is described in his "Great Operations of Surgery." Mr. Spence tells his pupils not to use it in cases where there is malignant disease, or much suppuration, lest unhealthy fluids should be forcibly distributed by the bandaging amongst healthy tissues. He also tells them not to employ it in cases of ligature of arteries. "I make these exceptions," he continues, "because I think that this form of bloodless surgery is liable to suffer from its indiscriminate use, and from over-laudation; but I have already said that I consider it a most valuable aid in proper cases, and it seems as if it were revived now with special relation to the progress of conservative surgery."

Mr. Spence speaks with great authority upon the subject of *injuries and diseases of blood-vessels*, and the twelve lectures devoted to it are full of interest, thought, and work. Under the head of *fractures* we learn that Mr. Spence, who was in former years a great advocate for the use of the long splint in fractures of the femur, has now entirely discarded it for the treatment of extension by the weight and pulley. In speaking of the treatment of the surgical neck of the humerus, he says: "The elbow is supported so as to keep the parts in position." (P. 291.) The hand and forearm should no doubt be well supported, but not the elbow. The author is apt to mislead the young surgeon when, in talking of the nasal mucous polypi (p. 95), he says that "a single twist of the forceps will remove the disease effectually." In substituting the word *osteo cystoma* for *spina ventosa*, Mr. Spence has done well, but it is a pity that he still employs that old term, *morbus coxarius*.

Mr. Spence expresses himself as being in favour of chloroform as an anæsthetic, but he says that when he is dealing with an aged patient, or with one with a feeble pulse, he mixes a little anhydrous sulphuric ether with the chloroform, "although for general use the chloroform answers far better." He advises that the patient be brought rapidly under the influence, believing that there is less danger in so doing than in beginning with small doses. He laughs at the measuring-bottle as merely giving an appearance of caution, and preparing for a coroner's inquest. This is, we think, very near the truth.

An important point in Mr. Spence's work is that he has given up performing Chopart's operation since the introduction of amputation at the ankle. Experience has shown him that it never leaves a very useful stump, and that it is far inferior to amputation at the ankle. He is not dictatorial on this matter; he merely gives us the result of his valuable and ripe experience. He tells his hearers that if they ever perform Chopart's amputation, he would advise them to divide the tendo-Achillis at the same time. He considers that Pirigoff's modification of amputation at the ankle-joint is anything but an improvement on it. Mr. Spence does well to be proud of the successful primary amputation at the hip-joint, which he alludes to every now and then. At one place five pages are devoted to the clinical history and remarks, and plate xli. gives us a full length portrait of what is left of his patient, supported in the upright position by a crutch. Earlier in the same volume nine pages are sprinkled over with statistics. It is a pity that here (as at a few other places) the text has not been condensed so as to have afforded the author room for entering on the subject of *artificial limbs*, for doing which he says that he felt very much tempted had his limits permitted.

In treating *cleft palate* no mention is made of Sir W. Fergusson's improvement of the operation in dealing with the gap in the superior maxillæ by cutting and moving pieces of the bone. Nor in the treatment of *strangulated hernia* is any mention made of puncturing the gut. In many, perhaps in most cases of strangulation, such treatment would do harm rather than good; but on the other hand, there are cases in which sufficient fluid or gas may be withdrawn to allow of the return of the gut. Such are the large and old standing ruptures, and perhaps the umbilical. In such cases the reviewer's puncture has been employed with success.

Mr. Spence prefers (1008) lithotrity to extreme dilatation of the urethra in cases of stone in the female bladder.

If we have referred somewhat critically to certain parts of Mr. Spence's book it is not with a view to find fault, but rather to call the author's attention to certain weak spots, so that when he is called upon for another edition it may be, as it naturally will be, nearer perfection. We should like to see the *clinical cases and commentaries* embodied in the text of the work in the usual course of the lectures. Thus they would have been more valuable to the student, and would have afforded material for fixing the author's remarks. As it is, they are scattered, collected in batches, in different parts of the two volumes. It is hardly likely that the ordinary reader will wade through half a page of a clinical clerk's work, which looks more like an auctioneer's catalogue than a pithy and well-considered report (v., pp. 684, 688). We cannot close our remarks without complimenting the author and the publisher on the illustrations, both plain and coloured. They are excellent, and will prove of great use to the young practitioner and the student. We doubt if any one could mistake a case of erysipelas after having seen the illustrations in plate iv. The uncoloured lithographs which represent the manipulation, apparatus, and method of applying bandages and so on, in *fractures* and *dislocations*, are clear and truthful.

◆

CLINICAL LECTURE ON A CASE OF CATARACT EXTRACTION. (a)

THIS is a lecture by Dr. Charles Bell Taylor, of Nottingham. Dr. Taylor narrates the case of a patient, aged 58, weighing only 6st. 3lbs., with cataract fully formed in the left eye, but not so fully formed in the right eye. She was, to all intents and purposes, blind, and had been so for upwards of a year. The tension of the eyeballs was slightly below par. The corneæ attenuated. The cataract had a hard yellow nucleus. As to the idea of reclination in this case, Dr. Taylor points out that 50 per cent. of such cases fail, and hence the only course left was to extract, removing a small portion of the iris. He would have preferred performing iridectomy first of all, and then removing the cataract some weeks afterwards, as was practised by Mooren, but that was out of the question in this case. Mooren operated in sixty-two exceptionally unfavourable cases in this manner, with only two failures.

Some of the best operators prefer the upper section of the corneæ, but Dr. Taylor seems to prefer the downward section. He would prefer to dispense with anæsthetics in the operation of extraction on account of the vomiting, congestion, and struggling which they occasion. Nitrous oxide is safe, and scarcely even causes vomiting, but it occasions struggling, spasm, and a kind of epileptic condition, so that insensibility can seldom be conveniently maintained until the operation is completed. Chloroform, bichloride of methylene, and methylene ether are pleasant to inhale, but they all cause vomiting, that form of vomiting sometimes lasting twenty-four hours, while the patient is with each of these exposed to the risk of fatal syncope, or death beginning at the heart. Ether is the only available anæsthetic with which he is acquainted with that is free from this special risk; this constitutes the real superiority of ether as an anæsthetic, and therefore he administered it in this case.

For the first two days after the operation suppuration seemed imminent, but the careful application of hot compresses, with a firm bandage, thrice daily, seemed to alleviate this state, and the other eye was operated only by downward section of the cornea.

◆

ON STETHOMETRY. (a)

THIS work supplies a want which must have been felt, more or less, by all. The author, too, must have devoted an unusual share of attention to the subject of which he treats; for though he speaks of his work being, as it were, elementary, it is in truth most elaborate, and the several points worked out to the fullest extent. We need not tell our readers that the object of the author is to advance our knowledge of the diseases of the chest by rendering the diagnosis the most exact possible. This special point, it is unnecessary to say, is one worthy of all attention. On no single point is a great physician seen more than on that of diagnosis, and it is certainly strange how many mistakes we are still capable of making. We believe that every one in turn makes some. But he is the greatest who makes the gravest, and the man who helps us to avoid them is a real benefactor to medicine.

We have no intention of entering at length into an analysis of the several chapters which compose this work. We may say, however, that after an introductory one, the author gives an account of the several modes which have been proposed for mapping out the chest. This is followed by a very elaborate account of the movements of the several parts of the thorax, and the causes of these movements. The reader will find some very curious points here in connection with the ribs and their motions. Then comes a description of the new instrument introduced by the author, and which he calls a stethograph. We cannot attempt to describe it, but must refer our readers to the work itself, and as it is illustrated, they will find no difficulty in understanding the instrument. In the following chapters the author shows how the instrument acts as a guide to diagnosis and treatment, and in the concluding chapter how the instrument aids in the prognosis of chest diseases. In the last chapter in particular several cases are given where the diagnosis was materially aided by the use of the stethometer. At the end of the volume the author has added an appendix on the nature and quantity of the organic matter contained in respired air. This latter subject, we need scarcely say, is one of much consequence and interest.

We had nearly forgotten to state that the volume is dedicated to Dr. Stokes, and seems to us a becoming compliment to one who has himself contributed so largely to our knowledge of thoracic diseases.

We can with confidence recommend this volume to the notice of our readers. They will find in it information which, as far as we know, does not exist in any other, and they will feel that after its perusal they have gained much in rendering the diagnosis of some of the diseases of the lungs far more accurate than hitherto.

◆

SIR WILLIAM FRAZER has given notice in the House of Commons that early next session he would move for leave to bring in a bill to amend the law relating to the sale of poisons and poisonous substances.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 30, 1876.

POLYPHARMACY.

IN the long and able address which Dr. Sieveking has just delivered before the British Medical Association, he draws attention to the good results which followed from the protest of the late Sir John Forbes against the polypharmacy of the day. Dr. Sieveking went so far as to assign to an article written by that eminent physician, on " Homœopathy, Allopathy, and Young Physic," the " maternity of a new era of the medical profession in its scientific position in her Majesty's dominions." There is, said he, a *vis destructrix*, as well as a *vis medicatrix* in nature, and which has to be met boldly and decisively. " But modern English medicine paid too exclusive attention to the latter, while it ignored the former; it placed its trust in the *armamentarium pharmaceuticum* to an extent which we, of the present day, neither follow nor applaud. The trade spirit also had some part of these aberrations; hence it was but natural, as the laity discovered that they might put aside the customary six bottles a day, in addition to the pill at night and the draught in the morning, sent in (and charged for) by the family attendant, without necessarily becoming a unit in the Registrar's death list, that they often attributed a cure, which we know the *vis medicatrix* is capable of effecting in many cases, when aided by a suitable regimen, to an infinitesimal dose of sepia, pulsatilla, or nux."

It was, said Dr. Sieveking, not to be denied that when Forbes's article roused the indignation of his opponents, the elements in treatment which were allegorically represented by the old story of Dr. Diet, Dr. Quiet, and Dr. Merryman, had given place almost entirely to what was termed heroic methods. "Bleeding from the jugular vein and temporal artery, large and repeated doses of mercurial and antimonial preparations, constant venesection and leeching were in daily use; and it was not to be wondered at, that as physiology and pathology came to be more thoroughly studied, the difficulty of finding a satisfactory reply to an inquiry, why these things were done, should arrest the thoughtful practitioner. Homœopathy gave Sir John Forbes a rude shake, and he found it necessary to unlearn much and to retrace his steps, so as to recover the true path of nature. But it was only on the principle, *fas est et ab hoste doceri.* Forbes made himself the spokesman of many, who, by the support they rendered him, showed that while they recognised this error, they were as far as he was from regarding homœopathy as a development of science."

We think, however, the change which took place some years ago in our system of treating disease, was not of so sudden and timely a nature that it could be attributed to any one cause, or to the representation of any one writer, but rather to several causes which had been silently at work for years previously, and which cooperated in bringing about the results of which we are now speaking.

Although yielding to no one in our contempt for both the doctrine and the practice of homœopathy, we do not for a moment hesitate to allow that this system, irrational and absurd as it undoubtedly is in theory, had, independently of the writings of Forbes, no little influence in throwing discredit upon the wholesale drugging of patients which was then in vogue among general practitioners. Long before Sir John Forbes wrote the article above mentioned, the tenets and practice of Hahnemann had not only taken a strong hold on the upper classes of society, but had made a strong impression upon the minds of those people who, whether physicians or patients, still held fast to the principles of orthodox medicine. The apparent success with which the more simple and curable diseases were treated by homœopathists, taught the polypharmacists how much might be accomplished without the use of drugs, for no one having any pretention to common sense allowed that the globules of the homœopathists were anything but a delusion and a sham, or that their doctrine had any rational principles to rest upon; and consequently it was soon seen that the curative powers of nature were sufficient to explain all the apparent triumphs of their system.

Another cause which did much to stop the large and indiscriminate use of medicines then in vogue was, that a better and more thoughtful class of men were entering the ranks of the profession, and that the standard of medical education was daily becoming higher and more comprehensive; while at the same time our knowledge of pathology and of the natural tendency of disease was making great progress and opening our eyes to the fact that many diseases, even those of an acute and dangerous nature, tended to a spontaneous cure, or at all events were not to be cut short by the heroic remedies, or the large consumption of drugs, which were formerly resorted to. On this subject we would gladly dwell did our limits permit us, but we must hurry on to the consideration of other causes which also in no small degree contributed towards a wholesome reform in the treatment of disease.

In the first place, we shall allude to that spirit of scepticism which has from time to time raised its voice in our department, as in all other departments of human knowledge; and to those reactions which history shows us to have marked the progress of medicine, of politics, of religion, and indeed of all human actions and systems of belief. It can scarcely be denied that the expectant treatment so frequently followed at the present day, and the reliance that is now placed upon food and stimulants, instead of bleeding and antimony, are to be partly attributed to a reaction upon the old system of treatment, and for which reaction no adequate explanation can be given, or no other than that unstable state of public opinion which at all times, and on all subjects, often goes from one extreme to the other. If some of us have been taught to cure pneumonia with a little acetate of ammonia, and a poultice to the chest, it is because others before us attacked that disease with all the *armamentaria* of bleeding, calomel, opium, and antimony. If Todd poured down the throats of his patients pints of brandy, it was because Bouilland had before him bled his patients almost to death.

Nor ought we to forget to take into consideration the share which a possible change of type in disease, and the share which the prejudices of our patients themselves may have had in dealing all but a death-blow to the polypharmacy of former times. The hypothesis of a change of type in disease has been ridiculed by two classes of physicians—by those who, complacently viewing the progress of modern pathology, have attributed to this cause, and to this cause alone, the more cautious treatment of the present day; and by those who, although at first upholding the above hypothesis, have afterwards changed their views, being influenced more by public opinion than by their own convictions, or by a careful examination of the subject. If, however, we are to judge from the testimony of those who lived and practised in both those periods of which we are now speaking, we are warranted in concluding that the supposed change in the type of disease is something more than a mere hypothesis; and if it is highly probable that such a change has taken place, at least, to a certain extent, it follows that such a change may have had some effect in arresting the perturbative method of practice which formerly prevailed. We shall not, however, insist that a change of type in disease is even partly accountable for certain characteristics of modern therapeutics, but only suggest that it is a possible cause, and one that should not be lost sight of.

Less open to doubt is the influence which the prejudices and predilections of our patients themselves had upon the modern practice of medicine. It was not to be supposed that even the most faithful adherents to orthodox medicine could remain indifferent to the practice and apparent success of the homœopathists. Nor was it to be supposed that while their neighbours were expatiating on the marvellous effects of swallowing a few tasteless globules, they could keep from remonstrating against the customary six bottles a day, the pills every night, and the nauseous morning draughts. It was more than could be expected of them, and we know, as a fact, that they did remonstrate. Besides, at the time we are now speaking of, patients participated in the general scepticisms of the age; they had lost a good deal of that credulity and superstition, and that reverence for authority and opinion which characterised our ancestors; and one way in which they showed how much they were influenced by the rationalistic spirit of the times, was their aversion to the polypharmacy which was more or less forced upon them, and the readiness with which some of them adopted a plan of treatment the palatable nature of which was certainly no small recommendation.

Lastly, but by no means of least consideration, is the effect of that large share of attention which has been for the last twenty years devoted to hygienic reforms, and the study of State medicine. The impetus which has been recently given to the study and practice of this department of medicine, and the zeal which all parties have shown in improving the state of the public health and in preventing disease are well known to us all: and a little reflection will convince us that this devotion to preventive medicine, and this awakening to the good results to be expected from hygienic practices, had no small share in diverting the minds of medical men from the question of treatment, especially that meddlesome treatment which so engrossed the attention of the practitioner of the past.

Such is our view of the causes which have led to a more rational system of therapeutics, and the influence of which might have been more fully illustrated and made more striking had the scope of this article permitted us to do so. As yet, too, we have only spoken of the polypharmacy of the past; but we hope to have an early opportunity of showing that a certain phase of this polypharmacy still survives amongst us. We may then also think it worth while to question the propriety of wholly giving up the traditions and practices of our predecessors—and to consider whether, by steering a middle course between the old heroic method of grappling with disease and the *laissez faire* system of some modern practitioners, we may not be acting in accordance with the suggestions of a sound pathology and a proper estimate of the resources of modern therapeutics.

◆

SUMMER DIARRHŒA.

THIS is a very common ailment at this period of the year. A great many different hypotheses have been put forward in order to explain its occurrence. Perhaps of all these so-called explanations, the one which has met with most favour has been that of its origin in eating fruit. The fact that fruit begins to be plentiful in hot weather, especially towards the latter part of July and through August, and that this is the time when summer diarrhœa shows itself most strongly, is too suggestive for many minds to carefully examine the evidence so furnished of this association. That the mortality is greatest amidst children under one year of age, who cannot help themselves to fruit, and who, as a rule, have not fruit given to them, is fatal to this captivating hypothesis. So strong, however, is the impression that fruit is the chief provocative of summer diarrhœa, that children are largely denied this form of food, though one peculiarly grateful to them; and, as a consequence, when opportunity offers, they are apt to gorge themselves with fruit, often of an unwholesome character, and then, of course, diarrhœa is induced, and the mischievous hypothesis strengthened. It will do much towards allowing children a fair daily amount of ripe wholesome fruit, when it becomes generally known that summer diarrhœa has a totally different origin. The *Philadelphia Medical Times* of August 6th has a leader on "Sunstroke, or Thermic Fever," by its able editor, H. C. Wood, so favourably known to us by his unequalled work on "Therapeutics and Materia Medica." Dr. Wood has paid great attention to this matter of the production of disease by excessive heat, and the recent hot weather—which has been quite as excessive in Philadelphia as here —has given him unusual opportunities for its study. It appears that it may show itself in two forms, (1) that of collapse, with a temperature as low as 95·5 Fahr., the skin being bedewed with perspiration ; or in the (2) form of pyrexia, the temperature rising to 107·5. In the latter form cold baths are of the greatest service. (These observations of Dr. Wood's quite agree with what has been observed of sunstroke in India, and even at home this year.) A great number of cases of such thermic fever has been furnished by the centennial, and the cold bath gives great relief.

Dr. Wood goes on to say: "Such cases must be frequent during long spells of excessive heat. This appears to be especially the case with children. There can be little doubt that many of the cases reported as cholera infantum, enteritis, &c., are really instances of thermic fever, and are curable by treatment as such. Especially does this seem to be true of those cases in which the disease is popularly said to 'go to the head.' Cases of this character usually owe their cerebral symptoms either to intense exhaustion, to be treated by stimulants, or to intense fever, to be treated by cold baths. In the *Philadelphia Medical Times*, vol. v., p. 664, may be found a most valuable paper by Dr. C. G. Comegys, concerning the cold bath treatment of infantile 'summer complaint.' Any one who has seen, as I have this summer, the child in whom drugs had ceased to act, and who was seemingly doomed to die, relieved in twelve hours by enforced cold bathing every three or four hours, will grant to Dr. Comegys the credit of having introduced one of the most life-saving improvements in modern infantile therapeutics. The sudden sweet sleep, replacing, after the bath, the fretful nights and days of unrest, is a thing never to be forgotten when once seen, and the arrest of diarrhœa is certainly no less remarkable."

This is, indeed, a valuable addition to our means of treating infantile disorders, and one which brings out in strong relief the usefulness of the clinical thermometer. If in a case of diarrhœa in hot weather, it is found that the temperature continues to rise, then the thermic origin of it may be at once suspected. Purgation, as Wunderlich points out, is a potent means for lowering temperature, and ordinary diarrhœa is found along with a low body temperature. When the thermometer reads 101°, 102°, or even higher, in a case of diarrhœa in an infant, the cold bath should be resorted to without delay, and repeated till the temperature falls. It has been found that the administration of quinine is useful after the cold bath in thermic fever, and its use by subcutaneous injection might not be contra-indicated by the state of the bowels ; or it might be given by the mouth, along with [illegible]huric acid and infusion of hæmatoxylin.

These observations from Philadelphia are really most important, not only as to the best means of treating summer diarrhœa, but as tending to destroy the erroneous impression that fruit is the origin of the mischief. By this last effect children will largely benefit, as proper quantities of fruit are very useful for them ; quite as much so as for the adult, who finds that plenty of fruit keeps him cool and regulates his bowels.

◆

THE HOSPITAL SATURDAY FUND.

In another part of our columns will be found an account of the proceedings of the last meeting held by the board of delegates of the above fund at the Workman's Hall, Stratford.

It was, in the first instance, very kind of the representatives of the working classes to come forward in aid of the funds of those hospitals and dispensaries to which, in the hour of sickness, those classes are so much indebted. No doubt the hospital authorities feel the honour and the gratitude shown to them, and on the principle of never "looking a gift horse in the mouth," would be the last to find any fault with the manner in which they distribute the funds at their disposal. At the meeting, however, above referred to, the plan fixed upon for this year's Hospital Saturday distribution is so novel that we, who can express our opinions from a more independent platform, cannot help smiling at the ingenuity, and even the conceit, which characterises the scheme, even at the risk of being thought a little ill-natured and ungrateful.

In the first place, if we regard the very careful manner with which the council propose to divide the money available for distribution, and the anxiety they show lest any charity should get one penny more than it deserves, we involuntarily conclude that they place no small value upon their fund, and that they evidently wish to impress upon the hospital authorities a keen appreciation of the obligation imposed upon them. But what strikes us most of all is the remarkable, novel, and eccentric character of their scheme of relief. In fact, it reminds us of the pedantic system of rewards and punishment adopted in schools. The plan of regulating the amount to be awarded by a system of marks, the classification of the various subjects for which prizes are to be given, and the withdrawal of all reward where the party concerned has been guilty of bad conduct, reminds us of a school in which boys are rewarded according to their respective merit and good behaviour, their proficiency in learning, and the regularity of their attendance. Most marks are to be given for amount of work done, but economy and industry, and success at passcertain examinations will also be taken into account. Thus, the largest slice of the cake will be given to the boy who has been able to do most work, and who has generally distinguished himself during the last year, and the next largest to the boy who has scored most marks through his careful conduct and economy, and who has not spent his pocket money extravagantly. But a prize is also to be given for their efficiency, as shown by their written examination, one mark being awarded for every question answered to the satisfaction of the examiner. Moreover, as we have already hinted, punishments are to be awarded as well as prizes, and we are sorry to see that one boy, who has always borne an excellent character, has been threatened with the loss of his slice of the cake for alleged misconduct. His parents, however, have promised to investigate into his alleged misconduct, so that the gentlemen who decide as to the respective merits of the boys will for the present abstain from punishing him.

But not only does this method of dealing with our hospitals and dispensaries appear to us a little puerile and humiliating, but it must fail to give the most relief to those institutions which are most in need of it. If the amount to be distributed is to be "solely in proportion to the amount of relief afforded and the efficiency obtained," if one mark is to be given for each bed occupied per week, and one for every 200 atttendances of out-patients relieved during the last twelve months; and if, moreover, the money available for distribution is to be allotted in proportion to the number of marks obtained, it follows that the largest, the richest, and the best-endowed hospitals will get the largest share of the fund. It seems almost impossible that such can be the intention of the distributors of the fund, but the report before us distinctly states that "though questions have been asked each hospital and dispensary as to their several incomes for the past year, the distribution *shall be based solely upon the amount of relief afforded, the economy practised, and the efficiency attained.*"

With respect to the inquisitorial nature of the scheme, little fault can be found, as the wants, the condition, and the resources of an hospital must always be a guide to the distribution of such a fund. But independently of information on such a subject, the Hospital Saturday Fund will exact in accordance with its third principle:—(*c*) Efficiency—a very full and correct account of the efficiency of each hospital and dispensary. The hospital authorities, therefore, must be on their best behaviour, for if they answer the questions put to them "to the satisfaction of the Council," they will get plenty of marks, whereas if their answers are not to the satisfaction of this august body, they will get none, and no marks means no money.

◆

THE REGISTRAR-GENERAL'S QUARTERLY RETURNS.

We have on former occasions so fully noticed these returns that we shall, in respect of the one just issued, merely draw attention to a few of its more interesting features. We are first informed that the population of England has been increasing faster than usual by the excess of births over deaths, and by a decrease in emigrations, and that the birth-rate is remarkable as exceeding that which prevailed in the corresponding quarter of any preceding year since 1837, when civil registration began. The marriage-rate agreed with the average of the ten preceding corresponding quarters, but was particularly low in Cornwall, where great depression prevails in consequence of the unsatisfactory state of the mining interest. The death-rate for the quarter was equal to an annual rate of 20·9 per 1,000 of the estimated population; and it is rather remarkable that within recent years there has been a steady decline in the female death-rate. As usual, we find that in Lancashire the death-rate was very high, being 27·3 per 1000. As remarked in the last returns, "sanitary progress has been far more marked in urban than in rural districts," and, consequently, although the towns have the greatest mortality, they show the greatest improvement. So much is this the case, that in twenty of the largest towns, including London, the death-rate during the quarter averaged 22·6 per 1,000, which only exceeded the general urban rate by 0·5 per 1,000. With respect to infant mortality, which is generally so high, there has been a slight decline, but in North Wales there continues to prevail such an excessive rate of mortality among infants, that the Registrar-General considers it to be "deserving of notice and investigation." The deaths from the nine principal zymotic diseases are also below the average; the most fatal of them being measles. Scarlet-fever has been on the decline during the present year, but in one part of the Redruth district, known as Treleigh, the extraordinary prevalence and malignity of this fever is apparently connected with the fact that the inhabitants drink the water of a stream which is little better than an open sewer. We are also glad to find that typhus and typhoid fever are still on the decline, and that the death-rate from these fevers is now less than at any period since 1837.

In this report special attention is paid to the sanitary condition of our watering-places. The Registrar-General remarks that the vital importance of health reputation to watering-places, and the special risk to which they are exposed by the importation of cases of infectious disease, invest the sanitary organisation of such places of resort with peculiar importance. The neglect to provide hospital accommodation for the isolation of non-pauper cases of infectious disease in so many of our most popular watering-places is specified as evidence of a short-sighted sanitary policy much to be regretted. Watering-places, in regard to sewage, water-supply, and other essentials of sanitary organisation, "should endeavour to make themselves models for other urban sanitary districts." This, however, can scarcely be said to be the case, although the average sanitary condition of English watering-places, judged by their statistics of mortality during the second quarter of the year, "may be pronounced satisfactory."

◆

Notes on Current Topics.

The late Hours of Shopwomen.

About nine months ago we drew the attention of our readers to one of those reports which are annually issued by the inspectors of factories, and which contained a terrible revelation respecting female labour in the "Black Country," the moral and physical degradation of the women employed in that district, and the awful amount of juvenile depravity and disease, and of infant mortality, resulting from such a shameful state of things. But among the social abuses which form the subject of consideration in the report recently drawn up by Mr. Redgrave, our attention is directed to an evil which, although far from being of so disgraceful a nature, or fraught with such deplorable consequences as that which has reference to the female labourers in the colliery and iron districts, is nevertheless more widely spread, affects a larger number of our female population, and comes more under the daily observation of the best classes of society. There can be no doubt that the massing together and detention of a large number of young women in hot, stifling, and ill-ventilated rooms from morning to night, and the number of hours they are restricted to a standing posture, with little or no exercise in the open air, must have a very baneful influence upon their health, and predispose to a variety of complaints that may certainly be said to come under the category of "diseases of modern life." The evil, however, is so intimately connected with the conventionalisms of society and with class interests, that it is difficult to see how it is to be removed; and our only reason for alluding to the subject is to suggest that the medical profession might do something to check that readiness with which so many young women sacrifice the best part of their youth to the greed and selfishness of their employers. If medical men took every opportunity of representing the pernicious effects that may arise from young and delicate girls standing behind the counters of our crowded shops up to 11 or 12 o'clock at night; and if among the many humanitarian societies that are continually springing up, room could be found for one which might induce the public to give up late shopping and large orders at short notices, or which would encourage the devotion of a little more time to rest or pleasure, and a little less to business, there might be some hopes of mitigating or altogether removing an evil which is certainly no small blot upon modern civilisation.

A Dental Hospital for Dublin.

A MOVEMENT has been in progress in Dublin for several months, having for its object the establishment of a dental hospital on the same basis, but, necessarily, on a much smaller scale from its prototype in Leicester Square. The list of officers appears in the *British Journal of Dental Science* of the current month, and is as follows:

Consulting Physician.—Thomas Hayden, Esq., V.P., K. and Q.C.P.I.

Consulting Surgeons.—Edward D. Mapother, Esq., M.D., surgeon to St. Vincent's Hospital.

Dental Surgeons.—Frederick Ryding, Esq., L.D.S.; William B. Pearsall, Esq., F.R.C.S.I.; Henry Sherlock, Esq., L.R.C.S.I.; M. J. Bloom, Esq.; Francis M'Clean, Esq., L.F.P.S. Glasg.; John O'Duffy, Esq., M.O.S. Gt. Brit.

Hon. Treasurer.—J. H. Longford, Esq., M.O.S. Gt. Brit.

Hon. Secretary.—John O'Duffy, Esq., M.O.S. Gt. Brit.

The journal in which the list of officers appears supports the proposal with warmth, and anticipates for the new hospital a decided success. We concur both in the good wishes and the favourable expectations of our contemporary, for it seems to us an opprobrium to Ireland that a competent institution for the practice and teaching of dental surgery has not hitherto existed. We do not encourage the splitting-up of surgery into an indefinite number of specialities, and we disapprove of the establishment of separate institutions to do the work which can be or is already well done in general hospitals, but there can be no dispute that dental surgery is as much a specialty as ophthalmology, and that it has not yet been—as a general rule—and cannot well be provided for as a department of general surgery. It is no slight to the Dublin hospitals to say that in the great majority of them the scientific practice of dentistry is not even attempted, and in only one or two of the whole number is any dental surgeon even nominally attached to the staff. The poor population is therefore dependent upon the charitable services of individual dental surgeons, or upon the somewhat crude manipulation of students, and as a consequence is almost without resource when suffering from teeth diseases.

Nor is there any better provision for the teaching of dentistry in Ireland, for which neither clinical experience, special instruction, nor a proper diploma are available to the student of this branch of surgery; nor is it within the power of the recognised colleges to remedy such a condition of things, inasmuch as there has not hitherto existed any teaching machinery whatsoever. As the natural consequence of this state of things, the public in Ireland is to a great extent in the hands of practitioners of whose competency neither the guarantees of surgical qualification nor of apprenticeship are forthcoming.

It cannot be doubted that Ireland is large enough for a special school of dental surgery, and Dublin large enough for a very efficient dental hospital, and we hope that the movement now in hand may be the means of providing both.

Liebig's Extract of Beef.

THE selling by chemists of what is known as Liebig's Extract of Beef has been declared by the Glasgow magistrates to be an offence against the Excise, one of its ingredients being French port. Two Glasgow chemists have been fined £12 10s. for having sold the mixture without possessing a wine license.

International Medical Congress, Philadelphia.

THE International Medical Congress will be formally opened at noon on Monday, the 4th day of September. The sessions of the Congress and of its sections will be held in the university of Pennsylvania. The general meetings will be held daily, from 10 to 1 o'clock. The sections will meet at 2 o'clock. Luncheon for members of the Congress will be served daily in the university building, from 1 to 2 o'clock. On Wednesday evening, September 6th, Dr. J. J. Woodward, U.S.A., will address the Congress on the scientific work of the surgeon-general's bureau. The public dinner of the Congress will be given on Thursday evening, September 7th, at 7 o'clock.

Pyæmia Contracted from a Cow.

LAST week the coroner for the southern division of Kildare held an inquest on the body of a cattle doctor, who died of blood-poisoning. It was sworn that the deceased attended a sick cow in the neighbourhood; he had at the time a small abraded ulcer on his hand, like a boil. After he came home his hand and arm swelled, and the swelling extended to the other arm. Having heard the evidence of the medical attendant, the jury found "That the deceased died from pyæmia, the result of absorption of some animal poison through an abraded wound of hand.

Methylated Spirits for Dispensing.

IN a general order, issued by the Inland Revenue

Board, dated July 24th, 1876, the following paragraph in relation to methylated spirit occurs :—It is further ordered that in order to prevent the use of methylated spirit in the preparation of medicine for internal use, the respective officers immediately remind all wholesale or manufacturing chemists in their stations that such use of the spirit is strictly prohibited by the Act 29 & 30 Vic. c. 64, s. 8, and that the board do not consider the use of such spirit legal in any medicinal preparation except soap and compound camphor liniments. Any infringement of the Act should be at once reported to the Board by the supervisor, and a sample of the medicine sent to the laboratory at the chief office." From a report of the last meeting of the Pharmaceutical Council, we observe that this order has been noticed by them, and that they have undertaken to explain to the Board the desirability of allowing the use of methylated spirit in the case of the liniments of aconite and belladonna.

We solicit also the particular attention of certain drug contractors for Irish union workhouses who are wont to supply tinctures—doubtless for philanthropic reasons—to the sick paupers at considerably less than the cost of the rectified spirit of which those tinctures are supposed to be made. If the Board of Inland Revenue see fit to devote themselves to a search through the Irish dispensaries they may probably find something to their advantage.

The Poisonous Strength of some Homœopathic Tinctures.

THERE is still a very general opinion that in all the homœopathic preparations of poisonous drugs the quantity of medicine contained in them is so immeasurably small, that a whole bottle of these tinctures, or a whole box of globules, might be swallowed with impunity. This was the opinion entertained at the recent inquiry into the death of Mr. Bravo, in which no notice was taken of "poisons all about the house," as that expression was said in reference to a lot of homœopathic remedies which some of the inmates had been in the habit of using. It is, however, so important that the mind of the public should be disabused of this false impression, that we shall direct attention to a paper which appeared some time ago in the *Practitioner*, and in which Dr. Robert Farquharson made some excellent remarks on the strength of certain homœopathic tinctures, and the evil consequences liable to result therefrom.

Dr. Farquharson found that the injection of fifteen drops of the strong or mother tincture of aconite was sufficient to kill a rabbit. This tincture appeared to be about equal in strength to that of our liniment of aconite, which we all know to be a much stronger preparation than the tincture of the British Pharmacopœia. The mother tincture of belladonna was next submitted to experiment, and was also found to be much stronger than our own tincture, five or six ten minim doses being sufficient to produce well-marked physiological symptoms of that drug, whereas fifteen or twenty minim doses of the tincture of the British Pharmacopœia may be often given without producing any such effect. Dr. Farquharson then turned his attention to the notable preparations of the homœopathists, some of which were carefully analysed by Mr. Broonen, the able analytical chemist of Messrs. Savory and Moore. One solution containing arsenic was labelled "Arsenicum Alb Poison. Dose for an adult, one to five drops," and was found to contain one grain of arsenious acid in 102 minims of water; while the corresponding solution used by the regular practitioner contains one grain of the acid to 120 minims of solvent. Another solution containing corrosive sublimate, and labelled "Mercurius Cor. Poison. Dose for an adult, one to five drops," was found to be four times the strength of the corresponding solution of the British Pharmacopœia. Dr. Farquharson justly remarks that although these preparations were labelled "poison," it is doubtful how far they were freely sold ; but that, at all events, "the ground is cut from under the feet of the homœopathist, one of whose great boasts used to be that no mercury or injurious metallic substance was ever prescribed by any of their practitioners." But they cannot, without exposing their knavery, dispense with the appearance of infinitesimal doses and minute sub-division ; and hence their inducement to adopt an excessive concentration of these powerful drugs, in order that their patients may suppose they are prescribing only a minute quantity of the remedy employed. Fortunately, the homœopathic amateurs who dabble in drops and globules use the third dilutions, which in all probability are powerless for good or evil. But when we bear in mind that the more potent mother tinctures are quite open to the public, Dr. Farquharson cannot be said to magnify the danger which may be apprehended from the unrestricted sale of such strong preparations, and which dangers he enumerates as follows :—1. The free purchasing of these poisons with homicidal or suicidal intentions. 2. The prescribing of them by old-fashioned homœopathists under the impression that they are perfectly harmless. 3. The great probability of the mother tinctures being mistaken for some of the dilutions ; and (4) the possibility of some of these strong tinctures being mistaken for the corresponding preparations of our own.

We may remark, in conclusion, that Dr. Farquharson gives full credit to Dr. George Johnson for having been the first to point out the strength of some of these homœopathic remedies. Several cases have come under Dr. Johnson's observation, in which the administration of the homœopathic solution of camphor had been attended with serious consequences. Considering the freedom with which this solution is used in domestic medicine, it is as well to know that it contains one ounce of camphor to one and a-half ounces of spirit, being stronger than the spirit of the pale brandy, in the proportion of seven to one.

The Army Medical Department.

WE understand that of the 44 candidates whom Mr. Gathorne Hardy had netted to "compete,"—save the mark ! for 77 army surgeoncies only 25 actually came to the scratch at the recent examination.

The department is not likely to be saucy about the quality of the answering and will, of course, be glad to take any candidate whom the examiners can stretch their conscience to recommend, yet it is not likely that more than 15 of the 25 competitors will achieve even this humble standard.

The "tea and turn-out" scheme of the War Office has thus culminated in just a baker's dozen of students upon whom the army waits for a reinforcement of its medical staff. Mr. Hardy and his colleagues deserve no better success, and we wish them joy of the *fiasco* and courage to answer the House of Commons when it reassembles.

We have, through the progress of all these miserable tinkerings of the army medical system, refrained from urging candidates to hold back from the competition because we did not wish to exercise a coercion upon the department, but preferred to give its proposals a fair chance with students. We do not hesitate now to advise candidates with all earnestness for their own sakes to refrain from entering the service, for we can promise them, if they will only wait a few months or a year, they will obtain a return in the way of advantages which will amply repay them for the delay.

Things are coming to their worst with the Army Medical Department. If another session of Parliament opens and finds the troops as they now are without adequate medical attendance and the temptations of the War Office despised as they have been, Parliament will, if we do not greatly mistake, insist on the emancipation of the service from combatant jealousies and official obstruction, and will awake to the necessity of dealing with medical men as with all other servants of the Crown.

A Knife-blade Fixed for Years in the Pleural Cavity.

In the New York *Medical Record* for July 22 there is a curious account of an autopsy of a patient about thirty years old, who had died of pulmonary consumption on July 8, 1875, and in whom a knife-blade was found in the left pleural cavity. It was three inches long, half an inch wide, and was lodged between the third and fourth ribs, at the inner border of the left scapula, lying in a slanting position and the edge forwards. The wound by which it had entered was indicated by a small and now adherent cicatrix about an inch above. This patient had been an inmate of penal institutions for about half of his life, and the reporter states from personal knowledge that the wound had not been received within four years of his death, and the presence of the foreign body was wholly unsuspected by those who had charge of him, the patient doubtless having reasons for not calling attention to it. Further inquiry rendered it probable that the injury was received in a quarrel in 1868 or 1869. Moreover, the reporter does not regard the foreign body as the probable cause of his phthisis.

Sea Water in the Treatment of Obesity.

In a recent number of the *Paris Médicale* we have some remarks on the treatment of obesity by the administration of sea-water combined with a residence at the seaside. Sea-water taken internally acts as a diuretic and purgative, particularly the latter. A small glassful of it should be taken three times a day in a little fresh water or milk. Sea-water baths are also to be resorted to, free exercise should be practised, and fattening articles of food strictly avoided. It is stated that sea-water used in this manner facilitates the oxygenation of the blood, and that it hastens the elimination of effete materials.

Cisterns and Waste Pipes.

In a report which has been recently issued by Mr. F. Bolton, examiner of the water supplied by the Metropolitan Water Companies, attention is drawn to a source of contamination of the water and even the air of private houses, which, although often been pointed out before, is too frequently overlooked by the householder. The contamination of water from the gases generated by sewage is, remarks Mr. Bolton, of far more frequent occurrence than is generally understood. Waste pipes from cisterns are frequently found to be in direct communication with the sewers. The gases thus flow back into the cisterns and become absorbed by the water. To prevent this, No. 14 of the Regulations should be strictly observed, the overflow pipe being brought outside the house and the end left exposed to the air, instead of being carried into the drain as is often the case. The adoption of this plan will get rid of the poisonous effluvia and gases from the drains, which would otherwise ascend through the pipe, and not only be partly absorbed by the water in the cistern, but be mixed with the air in the houses, thereby becoming a cause of fever and disease. The water delivered for domestic purposes by the Metropolitan Water Companies is frequently deteriorated after leaving the water companies mains by the dirty state of the cisterns on the premises of the consumers; and many of the cisterns, tanks, and butts for containing water in small tenement houses in the metropolis are in a disgusting and filthy state. An opportunity for inspecting these presents itself when travelling on some of the metropolitan and suburban lines. Cisterns will be seen without lids, full of rank and decaying vegetation, which on closer examination would show more or less organic deposit, and under the microscope would be found to abound in infusorial life. All cisterns should, therefore, be frequently cleaned out, more especially at the present season of the year, and every care should be taken to prevent the contamination of the domestic water supply after delivery.

We can vouch for the truth of the above remarks from our own personal observations; and we know for a fact that the companies often get blamed for their water, the dirty appearance and the smell of which have been entirely owing to the gross neglect and filthy habits of those to whom it is supplied. It is not only among the poor, but among the middle and higher classes, that the cisterns are apt to get into a dirty state. The cisterns should not only be occasionally and thoroughly cleaned out, as above directed, but just before the fresh supply of water comes in, that which remains in the cistern should be allowed to escape, and all the taps kept turned on for a few minutes after the fresh water has commenced to flow in. By this means the bottom and every corner of the cistern are kept perfectly clean and free from deposit, while it is impossible for the water, which is thus frequently renewed, to become impregnated in any appreciable degree with any gaseous impurities from the waste-pipe.

Diagnosis of Empyema.

Up to the present time, remarks the *Revue Médicale*, we have been able to recognise the existence of fluid in the pleural cavity, but we have no means of knowing the nature of the liquid effused. . . . . An Italian physician, however, of the name of Baccelli, and professor of clinical medicine in the University of Rome, has just published a remarkable work on the physical diagnosis of this disease, in which he points out a method of distinguishing between a serous and a purulent effusion. This method is founded upon the well-known physical law in virtue of which vibrations of sound are transmitted through liquids in inverse proportion to that of their density: being transmitted but feebly if the liquid is very dense, with force if it is limpid. Baccelli finds that a word spoken in a bass voice can be clearly heard, as well as the bronchial expiration, at the base of a serous effusion, whilst neither the voice nor the bronchial breathing is transmitted through a collection of pus. But for this method to be successful two conditions are necessary: 1. The naked ear should be closely applied to the chest without the aid of the stethoscope, and the ear which is free should be plugged with the finger in order to shut out all external sounds. 2. The patient should be placed in such a position that when he speaks, tne vibration of his voice penetrates in a direction diametrically opposed to the ear of the observer. Thus, supposing we are listening to the back part of the right lung, the patient's head should be turned to the left, in such a manner that an imaginary line drawn from his mouth to the ear of the observer passes obliquely from above downwards through the centre of the effusion. Professor Baccelli relates several cases in which the success of his method was proved by the result of the customary operation. This Italian physician makes his patient repeat the word *trenta-tre* as being the most favourable to the application of the above plan—a word which could be easily replaced by any French or English word consisting of three sonorous syllables.

British Pharmaceutical Conference.

THE following is a list of the papers that up to the present time have been promised for reading at the thirteenth Annual Meeting of the Conference, to be held in Glasgow, on Tuesday and Wednesday, September 5th and 6th :—

1. Liquid Extract of Pareira. Mr. Barnard S. Proctor.
2. Variation in the Strength of the Preparations of Opium. Mr. D. B. Dott.
3. Report on the Assay of Opium for Morphia. E. L. Cleaver. F.C.S.
4. Note on the Assay of Opium. Mr. Barnard S. Proctor.
5. New Derivatives from the Opium Alkaloids. Dr. Wright, F.C.S.
6. The Presence of Free Acetic Acid in Opium. David Brown, F.C.S.
7. New Excipients for the Official and other Pill Masses. Mr. G. Welborn.
8 The Preparation and Preservation of Phosphorus Pills. Mr. T. Haffenden.
9. Notes on some Salts of Pilocarpine. Mr. A. W. Gerrard.
10. Report on the Aconite Alkaloids. Dr. Wright, F.C.S.
11. The Solubility of Cinchona Principles in Glycerine. Mr. T. Andrews.
12. The Therapeutic Value of the Aloins. Dr. Tilden, F.C.S.
13. The Active Principle of Capsicum Fruit. J. C. Thresh, F.C.S.
14. Report on the Oxidation of the Essential Oils. Part IV. C. T. Kingzett, F.C.S.
15. Report on the Essential Oil of Sage. M. M. P. Muir, F.C.S.
16. Note on the Benzoates in Suint. Mr. A. Taylor.
17. Note on the Colouring Matter of *Crocus sativus.* W. W. Stoddart, F.C.S.
18. Pekoe "Flower"—or, Hair of the Tea Leaf. T. B. Groves, F.C.S.
19. A New Form of Plaster of Cantharides. Mr. A. W. Gerrard.
20. A Proposed Solution of Citrate of Iron and Quinine. Mr. J. F. Brown.
21. Preliminary Report on the Chemistry of Ivy. R. H. Davies, F.C.S.
22. Supplementary Note on Phosphate Syrups. W. L. Howie, F.C.S.
23. On Filtering Papers. Thomas Greenish, F.C.S.
24. Further Experiments on the Antiseptic Action of Salicylic Acid. Mr. J. C. Hunter.
25. Strength of the Tincture of Nux Vomica. L. Siebold, F.C.S.
26. Preparation of Milk of Sulphur. L. Siebold, F.C.S.
27. The Condition in which Salicylic Acid is excreted by Patients. F. B. Benger, F.C.S.

Fallibility of Analysts.

AT the Lambeth Police Court recently a tradesman appeared to answer a summons for having sold arrowroot which was said by Dr. Bernays, upon analysis, to be adulterated with potato flour, &c. A duplicate sample had been submitted by the firm from whom the arrowroot had been originally purchased to Dr. Saunders, the City analyst, who pronounced it to be a fine sample of St. Vincent arrowroot, and pure. The case at the first hearing having been adjourned in order that the sample might be examined by the Somerset House officials, a certificate signed by Mr. Bell and two other analysts was now produced, wherein the sample was declared to be pure arrowroot. Professor A. J. Bernays now reported to the sitting magistrate that, since the adjournment he had re-examined the sample taken from the defendant and found that he had made a mistake, for which he tendered an apology. An application was made for the costs, amounting to £2 10s. 6d., which were ordered to be paid—we presume by the analyst. There is, and could be, no excuse whatever for such gross negligence, and if the vendors of the arrowroot obtained damages against the analyst he would richly deserve his punishment.

An officer who is specially retained for legal investigation and to give opinions *ex cathedra*, and who has reason to expect that he will be examined on oath, has no palliation for his incompetency or carelessness, and we sympathise with tradesmen in the loss and inconvenience they suffer under such circumstances.

Coroners and Magistrates.

AT a meeting of the justices of the County of Middlesex held last Thursday, the vexed question of salaries of the coroners of the county once more came up for discussion, and as usual excited the ire of that portion of the magistracy who seem to be anxious to effect a saving in the county rates. The majority of the members of the court present on this occasion were of the class of retired tradesmen who can only view the question of remuneration of professional labour from their own standpoint in the grumbling, cheeseparing spirit of the class from which they have sprung. Dr. Hardwicke appears as usual to come in for their severe animadversion, for he, more than his colleagues, is always thought by his masters to be holding an unnecessary number of inquests, some eleven more than Mr. Humphreys, consequently his bill of costs is a few pounds more. His charges were, on this account, declared to be "unsatisfactory," and, in the indignant language of the chairman, "showing a disparity which ought not to exist." These magnates see no reason why Dr. Hardwicke, whose district lies far and wide, and compels him to travel dozens of miles and devote his whole time to his arduous duties, should ask to be fairly remunerated for his extra labour and cost of travelling. As to the charge brought against him of holding an unnecessary number of inquests he must be the best judge of this. We only know that a vast number of deaths, especially of infants, occur without any kind of judicial inquiry taking place to determine how and by what means death took place, and to these just justices of the county human life must appear of far less importance than the saving of a few pounds.

In the report of the proceedings it appears that the question of a further increase of remuneration to the coroners was discussed, and a letter was read from the Secretary of State, who reminds the magistrates of their duty by telling them that "for increased work the Act of Parliament enables them to award increased pay." Mr. Cross further states that "if an increased number of inquests have been held, and an increased expense of mileage incurred, such elements should not be *entirely left out of the calculation* in arriving at the basis of what is a fair salary to be paid to the coroners." In defiance, however, of this plainly written opinion, the magistrates had the impertinence to pass a resolution to the effect "that, having no means of discovering in what cases inquests were fairly held, and having a reason for believing that a large number were unnecessary and improper, they declined to make any increase in the salaries of the coroners of the county." Can anything be more unjust and iniquitous on the part of gentlemen holding Her Majesty's Commission of the Peace?

On Thursday morning last Mr. Rawdon Macnamara laid bare the right subclavian artery, external to the scalenus muscle, in one of his patients in the Meath Hospital, suffering under axillary aneurism, and compressed the vessel with Mr. Porter's "presse artére." The operation was attended with unusual difficulties in consequence of the displacement of parts, especially of the clavicle upwards, resulting on the great size of the aneurism; these difficulties, however, were all successively overcome, and the operation was performed with such an amount of caution and of skill that the patient did not lose a teaspoonful of blood. Up to the time of our latest report the patient was doing well. The case is of especial interest as a contribution to the surgery of aneurism, to the study of which the Irish school has long devoted itself, and in which it has earned well-deserved distinction by having given birth to the "compression" system. Should Mr. Macnamara's case turn out as satisfactorily as appearances promise, it will prove to be a valuable modification of the treatment advocated by Bellingham, Tufnell, Porter, and other surgeons of equal note.

The Medical Defence Association has been busy in prosecuting some rather flagrant cases of infringement of the Medical Act. A Mr. Witherington, chemist, of Wandsworth Road, was fined £15 and £2 18s. 6d. costs for using the title "Dr." on labels, &c., and having the word surgeon on a lamp over his door. On July 5, W. Walton Spiller, of 189 High Street, Shadwell, was fined £20 at the Thames Police Court for calling himself "Dr. Walton," and having the words "Walton, surgeon," on his door. The defendant said he called himself "venereal surgeon." The magistrate said this was both an admission and an aggravation of the offence. On July 22 another chemist, named T. C. Balls, of 2 Grange Road, Bermondsey, was fined £5 by Mr. Benson at the Southwark Police Court for unlawfully professing to be a surgeon.

The following tables, which are published by the Irish Local Government Board, show in each province where small-pox prevailed to the greatest extent within the last year, and the quarters of the year when it most prevailed:—

Summary of Small-pox cases attended by Dispensary Medical Officers during the year ended 30*th September,* 1875,—*taken from their quarterly returns.*

Provinces.	Quarter, 31st Dec., 1874.	Quarter, 31st Mar., 1875.	Quarter, 30th June 1875.	Quarter, 30th Sept. 1875.	Total
Ulster - -	41	27	41	37	146
Munster - -	8	—	—	—	8
Leinster - -	—	5	47	1	53
Connaught - -	160	218	251	57	674
Total Ireland	209	250	339	83	881

Deaths from Small-pox during the year ended 31*st December,* 1875, *abstracted from the returns of the Registrar-General.*

Provinces.	1st Quarter, 31st Mar., 1875.	2nd Quarter, 30th June 1875.	3rd Quarter, 30th Sept. 1875.	4th Quarter, 31st Dec., 1875.	Total.
Ulster - -	7	13	5	5	30
Munster - -	8	—	—	1	9
Leinster - -	2	8	—	—	10
Connaught - -	222	204	63	5	494
Total Ireland	239	225	68	11	543

The returns of the Registrar-General exhibit an increase in the deaths by small-pox from 540 in 1874 to 543 in 1875.

Madame Hagelle, of Paris, has given ten million francs to found a hospital for incurables at Paris.

Correspondence.

PROVIDENT DISPENSARIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Only that your correspondent, "Nemo," has published his letter concerning me in your journal, which has such a wide circulation in Ireland, where I have obtained my degrees, I should think it beneath my consideration to reply. The subject of provident dispensaries has already been well ventilated in most of the London medical journals, but as your correspondent is "Nemo," he cannot have read the reports, and therefore he does not know that there are over one hundred medical men in London alone who have similar institutions, and attend the poor for even much smaller fees than what I charge. That the main fact in his letter is utterly untrue I shall prove; but first, it is certainly the case that I attend the very poor (who would otherwise have to apply to the parish for relief) for small fees, but in *every* case I make it a certain rule to ask a new patient if he is one of the working class, and if he be not he is in all respects treated as a private patient, and charged probably as high a fee as "Nemo" himself charges. Fully one-third of my 3,000 patients were private, and paid the ordinary fees. "Nemo" has found out one or two "well-to-do tradespeople" who have evidently misrepresented their circumstances to me, and from this fact he, as a *good logician*, argues that I attend all grades alike. His letter is evidently that of a thoughtless and spiteful man; but, unfortunately for his pocket, it will not have the effect intended.

I remain, Sir, yours faithfully,

GEORGE A. LEWIS.

214 Old Kent Road, Aug. 21, 1876.

⁂ We cannot agree with Mr. Lewis that "Nemo's" remarks, published last week, are spiteful. It is the duty of every medical man to make known in the medical journals actions which he considers to be unprofessional, in order that they may be fairly discussed, and if wrong, prevented. Mr. Lewis admits in his letter that well-to-do tradesmen can, and do obtain his medical services for an inordinately low fee, and therefore "Nemo" has a right to complain.

There is nothing to prevent any man from giving advice and medicines for a very small fee, or even gratuitously if he will, but the question at issue is one of wider importance. The profession must set their faces against private provident dispensaries. Without referring to the institution of Mr. Lewis, against whom, as a professional man, we have no cause to complain, more than that in this matter his opinion differs from ours, we cannot conceive it possible that one man can by himself undertake charity on a large scale; much less can a medical man struggling for existence, such as is the case with many who open these so-called private provident dispensaries, do full justice to the cases which come before him, and also find the expensive medicines required for their treatment, for a sum which in some instances is so small that it would barely pay the cost of the medicines. We are quite of opinion that provident dispensaries well managed are useful institutions, enabling the poor to obtain medical services and treatment for a small sum of money, instead of them depending entirely upon charity. In this way they may be taught to respect themselves, and to save rather than to rely upon their pauperism to obtain all their requirements. Furthermore, the poor certainly have a greater regard for medical advice for which they have to pay than for medical advice literally hawked upon them as it now is by the numerous free hospitals, dispensaries, parish, &c. Necessarily, a great many expenses are entailed, besides a very great deal of labour, in carrying on the work of a provident dispensary, and if worked by one man, who has an object in making his private institution pay, it is liable to the very greatest abuse. He would naturally desire to get *through* the greatest number of cases in the smallest space of time, and would thus fail to recognise important symptoms upon which the whole treatment should depend, whilst at the same time he would be prejudiced to supply the cheapest remedies, when under other circumstances he would recognise the necessity of the expensive drugs.

We doubt not that Mr. Lewis will, on mature consideration, see the truthfulness of our remarks, and we would suggest to him that if he, assisted by his local *confrères*, would institute a provident dispensary under proper direction, and aided by subscribers, he would then enable the poor to obtain efficient advice and medicines for a small fee, instead of applying to the parish; whilst he himself would obtain some small remuneration for his service, and would at the same time avoid the ill-feeling which some of his neighbouring brother practitioners now have towards him.—ED.

◆

SUNSTROKE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—An interesting case of sunstroke was recently mentioned to me by my friend, Mr. John Noble, retired surgeon, R.N. He informed me that he reported it in his medical journal for the Admiralty about six years since.

The patient was a ship's steward, who received the stroke at the time Mr. Noble's ship was stationed at Annesley Bay, during the Abyssinian war. When Mr. Noble was called in, the man was in a dying state, and he rapidly sank. The thermometer, in the axilla, stood at 112 degrees shortly before death. This case is noteworthy for two reasons—1st. It shows how much the raised temperature of the blood has to do with sunstoke, and encourages the practice of cold effusion in the treatment of similar cases. 2nd. It strengthens Dr. B. W. Richardson's opinion that death is inevitable in any disease if the temperature of the blood reaches as high as 110 degrees.

I am, your obedient servant,

J. M. WINN, M.D.

Harley Street, Aug. 23, 1876.

[Although recovery is rare when the temperature reaches 110°, yet cases of recovery with a much higher temperature are now on record; one in particular in which several thermometers registered over 120°.—ED. M. P. & C.]

◆

Medical News.

Hospital Saturday Fund.—The last meeting prior to Hospital Saturday of the Board of Delegates was held by special invitation at the Workman's Hall, Stratford. Captain Mercier, the chairman of the fund, in making the usual report on behalf of the Council, mentioned that the arrangements for this year's collection were very complete, and that there was every reason to anticipate a large measure of success. The various public bodies, including the Post-office, the Police, the Royal Mint, the Fire Brigade, the Dock, Railway, and Steam Packet Companies, were cordially co-operating, whilst the *employés* of upwards of 1,060 firms, in addition to the 1,000 firms who contributed last year, had given their adhesion to the movement. Attention was also drawn to the case of Jane Park, whose sad death at the Universty College Hospital had formed the subject of a coroner's inquiry. Great indignation was expressed, and a resolution was moved by Mr. Moss to exclude the hospital from this year's distribution. Dr. Pardye, who had been a student at University College Hospital, drew attention to a letter which had appeared in the *Lancet* from Dr. Kempe (the house-surgeon of University College Hospital), and also to the fact that the Hospital authorities were instituting an inquiry into the case. After considerable discussion the following resolution was, on the motion of Mr. Frewer, seconded by Mr. J. Hughes, unanimously carried—"That as the Hospital Saturday Board understands the hospital authorities are instituting a full investigation into the lamentable case of Jane Park, the board do abstain for the present from expressing any opinion with reference thereto." The plan for this year's Hospital Saturday distribution, which had been prepared by a sub-committee, and had been confirmed by the council, was, after considerable discussion, unatradesmen who can only view the question of remuneration of professional labour from their own standpoint in the grumbling, cheeseparing spirit of the class from which they have sprung. Dr. Hardwicke appears as usual to come in for their severe animadversion, for he, more than his colleagues, is always thought by his masters to be holding an unnecessary number of inquests, some eleven more than Mr. Humphreys, consequently his bill of costs is a few pounds more. His charges were, on this account, declared to be "unsatisfactory," and, in the indignant language of the chairman, "showing a disparity which ought not to exist." These magnates see no reason why Dr. Hardwicke, whose district lies far and wide, and compels him to travel dozens of miles and devote his whole time to his arduous duties, should ask to be fairly remunerated for his extra labour and cost of travelling. As to the charge brought against him of holding an unnecessary number of inquests he must be the best judge of this. We only know that a vast number of deaths, especially of infants, occur without any kind of judicial inquiry taking place to determine how and by what means death took place, and to these just justices of the county human life must appear of far less importance than the saving of a few pounds.

In the report of the proceedings it appears that the question of a further increase of remuneration to the coroners was discussed, and a letter was read from the Secretary of State, who reminds the magistrates of their duty by telling them that "for increased work the Act of Parliament enables them to award increased pay." Mr. Cross further states that "if an increased number of inquests have been held, and an increased expense of mileage incurred, such elements should not be *entirely left out of the calculation* in arriving at the basis of what is a fair salary to be paid to the coroners." In defiance, however, of this plainly written opinion, the magistrates had the impertinence to pass a resolution to the effect "that, having no means of discovering in what cases inquests were fairly held, and having a reason for believing that a large number were unnecessary and improper, they declined to make any increase in the salaries of the coroners of the county." Can anything be more unjust and iniquitous on the part of gentlemen holding Her Majesty's Commission of the Peace?

On Thursday morning last Mr. Rawdon Macnamara laid bare the right subclavian artery, external to the scalenus muscle, in one of his patients in the Meath Hospital, suffering under axillary aneurism, and compressed the vessel with Mr. Porter's "presse artère." The operation was attended with unusual difficulties in consequence of the displacement of parts, especially of the clavicle upwards, resulting on the great size of the aneurism; these difficulties, however, were all successively overcome, and the operation was performed with such an amount of caution and of skill that the patient did not lose a teaspoonful of blood. Up to the time of our latest report the patient was doing well. The case is of especial interest as a contribution to the surgery of aneurism, to the study of which the Irish school has long devoted itself, and in which it has earned well-deserved distinction by having given birth to the "compression" system. Should Mr. Macnamara's case turn out as satisfactorily as appearances promise, it will prove to be a valuable modification of the treatment advocated by Bellingham, Tufnell, Porter, and other surgeons of equal note.

The Medical Defence Association has been busy in prosecuting some rather flagrant cases of infringement of the Medical Act. A Mr. Witherington, chemist, of Wandsworth Road, was fined £15 and £2 18s. 6d. costs for using the title "Dr." on labels, &c., and having the word surgeon on a lamp over his door. On July 5, W. Walton Spiller, of 189 High Street, Shadwell, was fined £20 at the Thames Police Court for calling himself "Dr. Walton," and having the words "Walton, surgeon," on his door. The defendant said he called himself "venereal surgeon." The magistrate said this was both an admission and an aggravation of the offence. On July 22 another chemist, named T. C. Balls, of 2 Grange Road, Bermondsey, was fined £5 by Mr. Benson at the Southwark Police Court for unlawfully professing to be a surgeon.

The following tables, which are published by the Irish Local Government Board, show in each province where small-pox prevailed to the greatest extent within the last year, and the quarters of the year when it most prevailed:—

Summary of Small-pox cases attended by Dispensary Medical Officers during the year ended 30th September, 1875,—taken from their quarterly returns.

PROVIDENT DISPENS[illegible]

TO THE EDITOR OF THE MEDICAL [illegible]

SIR,—Only that your correspondent, [illegible]
lished his letter concerning me in your [illegible]
such a wide circulation in Ireland, [illegible]
my degrees, I should think it beneath my [illegible]
reply. The subject of provident dispensaries [illegible]
well ventilated in most of the London [illegible]
your correspondent is "Nemo," he [illegible]
ports, and therefore he does not know [illegible]
hundred medical men in London alone [illegible]
tutions, and attend the poor for even [illegible]
what I charge. That the main fact in [illegible]
untrue I shall prove; but first, it is [illegible]
attend the very poor (who would otherwise [illegible]
the parish for relief) for small fees, but in [illegible]
a certain rule to ask a new patient if he [illegible]
class, and if he be not he is in all [illegible]
patient, and charged probably as high a fee [illegible]
charges. Fully one-third of my 3,000 [illegible]
and paid the ordinary fees. "Nemo" [illegible]
two "well-to-do tradespeople" who have [illegible]
sented their circumstances to me, and from [illegible]
good logician, argues that I attend all [illegible]
is evidently that of a thoughtless and [illegible]
fortunately for his pocket, it will not have [illegible]

I remain, Sir, yours [illegible]

[illegible]

214 Old Kent Road, Aug. 21, 1876.

*** We cannot agree with Mr. Lewis [illegible]
marks, published last week, are [illegible]
every medical man to make known in [illegible]
actions which he considers to be [illegible]
they may be fairly discussed, and if [illegible]
Lewis admits in his letter that well-to-do [illegible]
do obtain his medical services for an [illegible]
therefore "Nemo" has a right to complain.

There is nothing to prevent any man from [illegible]
medicines for a very small fee, or even [illegible]
but the question at issue is one of [illegible]
profession must set their faces against [illegible]
pensaries. Without referring to the [illegible]
against whom, as a professional man, [illegible]
complain, more than that in this [illegible]
from ours, we cannot conceive it [illegible]
himself undertake charity on a large [illegible]
medical man struggling for existence [illegible]
many who open these so-called [illegible]
do full justice to the cases which [illegible]
find the expensive medicines required [illegible]
a sum which in some instances is [illegible]
pay the cost of the medicines. [illegible]
provident dispensaries well [illegible]
enabling the poor to obtain [illegible]
small sum of money, instead [illegible]
upon charity. In this way [illegible]
themselves, and to save [illegible]
[illegible] to obtain all their [illegible]
[illegible] certainly have a [illegible]
[illegible] they have [illegible]

nimously adopted on the motion of Mr. A. W. Mackenzie. The plan is as follows :—That though questions have been asked each hospital and dispensary as to their several incomes for the past twelve months the distribution shall be based solely upon the amount of relief afforded, the economy practised, and the efficiency attained. The amount of relief afforded being the question of primary importance shall be the first taken into consideration, and a proportion of the total moneys available for distribution, equal to 75*l.* per cent. shall be allotted under the head of relief, the remaining 75*l.* per cent. being allotted in equal proportions under the heads of economy and efficiency. That the amounts to be awarded to each hospital or dispensary shall be determined by a system of marks on the following plan :—(A) Relief.—That one mark be given for each bed occupied per week, and one for every 200 attendances of out-patients relieved during the last twelve months. Marks to be totalled, and the money available for distribution to be allotted in the proportion of so much for each mark obtained. (B) Economy.—That the hospital and dispensary marks shall be awarded as follows—viz., hospitals at which the cost of in-patients per bed per week is 15s. or under, three marks ; 20s. or under, two marks ; 25s., one mark. Out-patients institutions at which the cost per head is 2s. or under, three marks ; 5s. or under, two marks ; and 8s. or under, one mark. The following institutions will receive special consideration under this :—Orthopœdic Hospitals and Surgical Appliance Societies. That of lying-in patients treated at their own homes, 25, shall be considered equal to one bed occupied per week. (C) Efficiency.—That the efficiency of each hospital and dispensary shall this year be determined by the information obtained from the answers to the general questions of the Hospital Saturday council ; that for every "general question" answered to the satisfaction of the council one mark shall be awarded ; where questions do not apply to institutions the committee will specially consider them. The marks awarded under the heads B and C to be totalled, and the remaining £25 per cent. of moneys available for distribution, for economy, and efficiency divided and allotted in like manner as under the head A in proportion so much for every mark.

◆

NOTICES TO CORRESPONDENTS.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Law respecting Periodicals, Newspapers, &c.—1. Subscribers who do not give express notice to the contrary, are considered as wishing to continue their subscriptions. 2. If subscribers order the discontinuance of their periodicals or newspapers, the publisher or publishers may continue to send them until all arrears are paid up, and Subscribers are held responsible for all numbers sent. 3 If Subscribers neglect or refuse to take the periodicals or newspapers from the office to which they are directed, they are held responsible till they have settled their bills. Sending numbers back, or leaving them in the office, is not such notice of discontinuance as the law requires. 4. If Subscribers remove to other places without informing the publisher, and their periodicals or newspapers are sent to the former directions, they are held responsible.

Hospital Saturday Fund.—Hospital Committees, and those of kindred medical institutions who desire to participate in this years Hospital Saturday Distribution, but who have omitted to furnish to the Council of the Hospital Saturday Fund the information on which the Council will make their awards, are reminded that the time for supplying the required information has been extended to Hospital Saturday, 2nd September. Medical institutions, the committees of which neglect to send in returns by the 2nd September will necessarily be excluded from this year's distribution, the plan of which has already been prepared. As in the two previous years, the distribution will be made equitably to each institution, according to the amount of Relief given, Economy practised, and Efficiency attained.

HOW TO MAKE LEECHES BITE.

To the Editor of the Medical Press and Circular.

Sir,—With your permission I would suggest to your readers a simpler and quicker way of applying leeches than that quoted in your journal of the 9th inst. It is this : get an apple, cut a slice off the top, then scoop out the centre, put the leeches into the cavity and apply over the part required. I have for some time tried this plan and have never been disappointed, as I found them to take instantly they are applied. Of course when the number to be used is large a large apple must be used, or two or more small ones.

Faithfully yours,

Parsonstown, James P. Myles, L.R.C.P.E., L.R.C.S.E.
August 16, 1876.

FEES TO MEDICAL WITNESSES.

To the Editor of the Medical Press and Circular.

Dear Sir,—Is there any rule laid down by law for the granting of fees to a medical witness ? Is £1 a fair fee to offer a professional man for giving evidence under the Vaccination Act when defaulters are summoned, and where he has to drive eight miles to the court and pay cab hire and other expenses, besides losing a day out of his district.

Where I have been so hardly dealt with, if I thought it possible to claim a fee in each case I decidedly would apply for it. Can I legally do so ? Ought not the same rule hold good in those cases as in Crown prosecutions where the same medical man if engaged in different cases to give evidence gets a fee for each from the Crown.

I am, Sir,
"Only a Dispensary Doctor."

[The Clause of the Vaccination Amendment Act, 26 & 27 Vict., cap. 12, is as follows : The Guardians may direct proceedings to be instituted for the purpose of enforcing obedience to the provisions of this Act; and as to all expenses incurred in such proceedings, if the Justice or Justices before whom such proceedings are had, certify that such expenses ought to be allowed, such Justice or Justices shall ascertain the amount thereof, and such amount shall be payable out of the Poor Rates ; and such proceedings on account of neglect to have a child vaccinated may be taken at any time during the continuance of the neglect. It will be seen that it is quite optional in the magistrates to certify for prosecution fees, or to fix the amount of such remuneration, but the Guardians have no option but to pay on such certificate. The fee usually granted by the magistrates has been £2 2s., and it is the very least sum which a medical officer should receive for attendance at a distance from home. It would not be reasonable to claim a fee in such case, but the magistrates would, we are sure, certify for any reasonable fee on a remonstrance and representation of circumstances.—Ed. M. P. & C.]

IRISH POOR-LAW INTELLIGENCE.

CORRESPONDENCE.

THE PRESENT WORKING OF THE SANITARY ACTS IN IRELAND.

TO THE EDITOR.

SIR,—In my last letter I endeavoured to point out some of the causes which renders the Sanitary Act inoperative. They were chiefly mistakes in the framing of the law, and the entrusting its proper carrying out to those who are *most interested in its obstruction.* As you very happily put it in one of your leading articles, entrusting a jury of milkmen to examine adulterations in their fellow tradesmen's milk. I propose now to discuss some of the hindrances to the proper performance of the Public Health Acts which arise from their dealing with the customs of the people.

A Poor-law inspector once said to me, "we do not know what to do with the dung heaps." Now, to any one unacquainted with the Irish poor, this would seem a very ridiculous speech, and easily remedied by enforcing the law; whereas in reality it showed his deep knowledge of the subject, a knowledge which has since been received in high places. An Irish peasant's dung heap means not only a manufacture on a grand scale for typhoid fever, which unhappily it too often is, but it also means *always* his bread and butter, or to put it more properly, his potatoes and milk. The poor man calls it his "industry." He makes it useful in this way. His children gather whatever refuse they can, road scrapings, dead leaves, manure, &c. If the father possesses a donkey and cart, he collects ferns and other vegetable substances, which will rot. He gets some "butts" of earth from his master the farmer, and with the aid of water the whole is converted into very useful and often rich manure. So rich is it that it is eagerly bought up by the farmer, and at a good round sum too, or better still, the labourer gets his potato garden ploughed and free of rent for the manuring of it.

I am afraid, Sir, I am entering somewhat into political economy, but it is necessary to show what a difficulty underlies a seemingly simple subject.

Suppose that the labourer has no manure beds, he has to rent the potato garden from the farmer at a high price, his wretched wages (from 6s. to 3s. 9d. about here) are stopped until he pays for the garden, and all that time he has (with perhaps a family of seven or eight children), to run credit for bread, &c. Now contrast this man's case with one who has his potato garden free, and one cannot wonder why the Irish poor invariably almost have a manure heap, and that nothing sets them so frantic as a summons for its removal. But the dung heap not only has its relations with the poor man who makes it and lives by it, but Farmer O'Brannigan, P.L.G., has as great an interest in it, for he cannot make sufficient manure himself, and therefore relies for a supply on Pat Mulligan, to whom he has given a house, under often stringent terms, that he is to make a "handful of manure." Farmer O'Brannigan, P.L.G., depends often for his rent on his crops. Hence landlord, tenant, and labourer are equally and conjointly interested in the most fertile cause of fever in this country. That dung heaps *are* the most fertile cause of fever I think no dispensary medical officer will deny. The dung heaps of the poor are mainly composed of rotting vegetable matter (I might hint at the first cousinship of typhoid and ague, as Murchison has of the identity of the plague and typhus fever, were it not foreign to the matter). However, there is no doubt in my mind that at the turning and removal of the manure typhoid of a low type, often confounded by men of the old school with simple continuous fever, breaks out and is caused by the miasm and smell which arises.

When we review the subject I think everyone will acknowledge the wisdom of the remarks made by the Local Government Inspector:—We sanitary officers are on the horns of a dilemma; as the matter now stands, we must either allow typhoid fever to generate at will, or we must expose ourselves to the bitter enmity of the poor of our district, and to the no less certain snubbing, if not open hostility, of the Board of Guardians. Yet I think a remedy would be found, and that with the farmers shemselves. The labourer generally obtains his house—alas! how often his hovel—from the farmer. This house is generally built on the side of the road for obvious reasons. The farmer will not give any land to make a dung heap at the side or back of the house, as it encroaches on his land, hence poor Paddy the labourer must make his dung heap *in front*, he must have his pig (another very important and long since acknowledged item in the Irish labourer's finances), either in the house or at the front of it. The peasant, I repeat, cannot help it, and often I have heard them bitterly complain of the necessity for having the cesspool in front of the house.

A short bill to better the condition of labourer's cottages, with clauses compelling the owners of the cabins to have a place for manure and a pig stye at the side or back, and stringent and heavy penalties against having manure heaps in front, or tiles to the houses, would have more effect in stopping fever than that olla podrida of laws yclept 37 and 38 Vic., cap. 93, and would not interfere with agricultural interests. An improved condition of the dwellings of the poor, and compulsory removal to the hospital of the infected seen on red tickets, would do more to stop fever than any conglomeration of acts which could be put together.

I am, Sir, your obedient servant,

A DISPENSARY DOCTOR.

◆

COMPULSORY SUPERANNUATION.

TO THE EDITOR.

SIR,—I have just seen in your publication of this week a letter signed "One of the oldest P. L. Doctors," regarding the subject of the heading of this. It would appear from that gentleman's letter that he has been for the long period of 42 years a P. L. or dispensary medical officer, and yet he states that he is informed it would be *madenss* to resign; as he would not succeed in obtaining superannuation. This is, indeed, a very hard case, for if superannuation is to be got at all, or if it is anything beyond the mere name, surely this gentleman by rights and justice is entitled to it!

The letter, dated June the 20th, which appeared in your journal, which is referred to, and which is signed "An old P. L. M. D." I also saw. I am much surprised that till now no notice was taken of that letter by any member of the profession; as I consider the suggestions it contained were well deserving of attention!

Not the least was one that, the M. D's who are in Parliament (one particularly was named) might be respectfully urged to obtain, if possible, Compulsory Superannuation. If properly and earnestly set about, I do not see why the effort should not be successful, in fact, I believe it would undoubtedly be so. Too much apathy and want of union among ourselves, are the cause of no good result; added to these the well-off and more fortunate members of the profession *who have power and influence* do not sympathise with and assist their poorer brethren in this matter, that is of vital importance to the latter, so great, indeed as to give them some *little independence in their declining days!*

The law as it now stands regarding superannuation, and so long as it is to be decided by boards of guardians, may be looked upon as of *very little value.* The man before alluded to, after forty-two years' *hard toil*, is sufficient proof of the statement. A policeman when he has served twenty-one or twenty-five years is allowed a handsome pension, but the unfortunate, educated medical gentleman has no certainty to look forward to, no matter how long his service may be. It was hoped that the Irish Medical Association could have succeeded in getting the matter referred to, satisfactorily and finally settled before this; but it still looks far in the distance, and "hope deferred maketh the heart sick." The energy and perseverance of the National School Teachers in seeking successfully what they desired is an example for us to follow. I have only to say in conclusion that if superannuation is not to be obtained, let the idea of it be given up for ever, and let men not be led to expect what is not probable. As far as I can see, I cannot encourage any good hope; and so long as I perceive such a marked coldness and indifference on the part of members of the profession, I shall, though an humble individual, *cease to trouble myself or to take any farther interest in the matter.*

My best thanks are due to you—an expression in which I hope all the profession will cordially join—for your desire to advance at all times their interest by the use of your valuable paper, and by you yourself advocating their hitherto neglected claims.

I am, Sir,
Your obedient servant,
J. D. R. K.

August 8th, 1876.

[WHILE we concur to the fullest extent in the observations of our correspondent, we are sorry we cannot agree in his happy anticipation of success for a compulsory superannuation agitation. There would not at present be the remotest hope of success, and a futile effort would seriously damage the position of the profession in respect of other grievances of which the prospect of redress is now hopeful. The opinion of the Local Government Board, the ratepayers, and the Guardians is unanimous and explicit. They will not, as a principle, superannuate any medical officer who can do without a pension, no matter what his services may be, and they will resist tooth and nail any proposal to compel them to do so. Where superannuation has been refused, the apparent cause has always been either that the medical officer was well off in his circumstances, or was capable of continuing his work, and superannuations have been applied for and obtained by medical officers who—though their length of service entitled them to consideration—were quite capable of continuing work. In one case which occurs to us the medical officer having obtained superannuation on the ground of ill-health, and on the faith of medical certificates, got well in haste, married, purchased a general practice in England, and is now in the full work of a large and populous district. In other cases the superannuated medical officer continues in the enjoyment of lucrative and laborious private practice, and holds public appointments, and, though a rich man, receives the superannuation grant for the rest of his life. While we hold that a medical officer who is really incapable of doing his work efficiently should be entitled to superannuation as of right, we can sympathise with Guardians in their desire to keep the power of deciding the matter in their own hands. At some future time the subject may be agitated with good effect, but at present we can assure our readers that the question is not ripe.—ED. *M. P. & C.*]

◆

CHARGE AGAINST DR. JOHNSTON, MEDICAL OFFICER OF THE WESTPORT DISPENSARY DISTRICT.

The following letter addressed to the *Mayo Examiner* has been sent us for publication:—

SIR,—I regret that I am obliged, in self-defence, to call public attention to a report in your journal of the 17th ult., of proceedings of the Westport Dispensary Committee on the 13th ult. The proceedings of the Committee had reference to a report made by John Kane, of Knappabeg, in this parish, against Dr. Johnston, medical officer of the Westport Dispensary district, for culpable neglect of attending, on a red ticket, his wife, who died without medical treatment. The Committee assembled to consider also the judgment of the Local Government Board on that report, and to show reasons why the Committee should ask the Local Government Board to reverse its judgment; of which I give as reported an extract:—"Upon a careful consideration of the evidence, the Local Government Board are of opinion that Dr. Johnston appears to have neglected the prompt and effectual discharge of his duty in this case." And again:—"The Local Government Board think that Dr. Johnston should be called on by the Committee of Management to send in his resignation." The defence of the Committee in favour of Dr. Johnston, as appears from the report of their discussion, and from their resolution, seems to hinge upon one or two points—1st: "That Father MacEvilly did not consider Mrs. Kane's life in danger, and did not anoint her." The Committee is thus reported—"Father MacEvilly hesitated to administer the last sacraments to Mrs. Kane." Again—"Father MacEvilly churched the woman, but she was not annointed." And again—"By the observations of Father MacEvilly it will appear that the woman's life was not thought to be in danger." And in the resolution, unanimously adopted "amidst laughter," and forwarded to the Local Government Board, the following appears—"It appears that Mrs. Kane was churched, but we have reason to believe she was not annointed." 2nd: That the doctor was not urged by John Kane to proceed at once to attend his wife. The doctor is thus reported—"I do not think from Kane's manner, on the evening of the 11th, that he thought her life was in danger. I never saw a man so indifferent as Kane about my attendance on his wife." Now, Sir, I beg to state *in limine* what I stated publicly at the investigation, that I remained neutral in this case from the beginning, through motives of delicacy; but I will now add I was not indifferent. Therefore, as regards Dr. Johnston, whom I respect personally, I will not either exculpate or criminate. I leave all that to the public mind. As to the Committee, many of whom I respect individually, I deprecate the thought of using one word offensive to even the least of them; but I cannot be blamed for endeavouring to remove from the public mind the impression made on it by the action of the Committee, viz., that I *did, as a matter of fact,* neglect to discharge an *important and* vital duty. Now, I hold that if I, having *been called on* to attend Mrs. Kane, and having made up my mind that she was in danger of death, refused, or even neglected, to annoint her, I would have neglected my duty. And I believe that nineteen out of every twenty of your readers are of opinion that I did not annoint Mrs. Kane, *i.e.*, "I neglected my duty." And surely, it is most painful to any priest to have it gone over the world, on the authority of a respectable public board, without one word in the meantime of explanation or retraction, that he did actually neglect his duty. And, now sir I give you the real facts of the case, for the truth of which I challenge contradiction. On the 11th April last I was called on by John Kane to attend his wife, who was quite lately after her confinement. I arrived at John Kane's house before 12o'clock noon. When approaching his house I met John Kane. I inquired if the doctor had seen Mrs. Kane, my object being that if he had pronounced unfavourably I would have less difficulty in Churching her under the circumstances. But when I saw her "I did not hesitate to annoint her," after having administered to her previously two other Sacraments. And perceiving her writhing in agony of pain, and in the exercise of my judgment, in the absence of a medical man, having satisfied my mind that Mrs. Kane was in great danger of death, I also Churched her. And, moreover, I told John Kane and some female relatives who were there, my opinion regarding her, and I urged him to at once call in a doctor. Well, having read in your journal of the 17th ult. a report of the proceedings of the Dispensary Committee, and conscious that a groundless issue had been placed before the Local Government Board on which they were asked to reverse their judgment I at once laid before the Local Government Board the above facts (an official reply to which I received in due course), vouching for their truth, and contradicting the statements and resolution of the Committee as regards myself. With the action of the Local Government Board in reversing their former deliberate opinion in presence of my authenticated facts, I have nothing to do. On the next day, 18th ult., I wrote to the Dispensary Committee also by way of complaint and remonstrance, but after an interval of more than a fortnight that honourable Committee has not deigned the courtesy of a reply. Now, as regards John Kane, I without impugning the testimony or cavilling with the opinion of any person, beg to state that I believe in my soul every statement deposed to by him to be substantially, if not literally true. And as to his having been "indifferent," truth compels me to put on record that, in my experience I seldom met a man who appeared more really and sincerely afflicted than when he heard my opinion of his wife's dangerous illness. And I will add, that there did not, and does not, exist in this parish a married couple who lived for upwards of 20 years more harmoniously and happily together, and that fact can be attested by all the neighbours. And now, I beg to submit a question. Is it possible that a steady, intelligent, strictly religious man, who lived happily with his wife, who had left him nine children, the greater part of whom are helpless, and the youngest a baby a few days old, and who, with her aid, could hardly make ends meet, but whose death has thrown on him the care and support of such a helpless family. Is it, I would almost say credible, that such a husband would be indifferent about such a wife? Or did he become indifferent in proportion as he was urged by the priest, and her condition shown to be apparently hopeless? Now, John Kane has sworn he was not indifferent, that he urged the doctor again and again, ; that the doctor had promised to follow him immediately, that he waited up all night expecting him, and called secondly on him early next morning; and I believe almost every man in this parish credit John Kane's testimony.

I remain yours faithfully,

Jeremiah MacEvilly.

Aughagower, 4th August, 1876.

ROSCOMMON UNION.

At the usual weekly meeting of the Board of Guardians of the above union, held on Saturday, the following report from Dr. Heily, medical officer of the Roscommon Dispensary District, on scarlatina, was read :—

"I regret to state that scarlatina still continues on the increase. Five new cases in Henry Street in one house occupied by a tailor named Fahey. Words are inadequate to paint the scene I witnessed in the sick room on Thursday night, a short time before the death of one of the children—poisoned, I might say, by its mother's obstinacy in preventing the removal of the patients to the workhouse hospital from the pestilential place occupied by them—two grown-up boys in one wretched bed, three in another. Unless very stringent measures are adopted and the parents compelled to allow the removal of the sick to hospital, it is impossible to think that sanitary measures—no matter how carefully and anxiously carried out—can be of use. Hoping that compulsory removal will be ordered this day."

Mr. McDonnell said something should be done to check the spread of the disease. The doctor recommended compulsory removal to hospital, and the board should cooperate with him as far as possible.

The Chatrman believed that as a board of Guardians they had no power to compel persons to enter the workhouse or hospital, whatever they might do as magistrates.

Mr. Burke believed the disease would continue to extend so long as the people of Henry Street were encouraged to keep their children outside by giving them a liberal allowance of out-door relief. The way to compel them to enter the hospital was to discontinue giving them out-door relief.

General Mitchell knew the parents who apply the money given them as out-door relief to other purposes than the relief of their children. He thought the board would be acquitted of all responsibility if they offered to take the parties into the hospital, and that the large sums given at present as out-door relief should be discontinued.

Mr. Burke fully concurred. It was encouraging these persons to remain in their houses, where their sick children could not be properly attended to, to give them 8s. and 10s. per week out-door relief.

The Relieving Officer said he considered he was bound to give provisional relief in all cases where it was recommended by the doctor. He never gave relief to persons except on the certificate of Dr. Heily.

General Mitchell believed Dr. Heily was quite right in doing his utmost to have these persons removed to the hospital, where they could be properly nursed and cared, instead of leaving them to die in the miserable houses at present occupied by them.

After some more discussion it was agreed to refuse out-door relief in the case of Fahey, referred to in Dr. Heily's report, and the relieving officer was directed to bring all available pressure on the parties at present suffering from scarlatina in order to induce them to enter the hospital.

◆

SLIGO UNION.

CONSULTATION FEES.

Relieving Officer Feeny reported that he had received a requisition from Dr. Laird to procure the attendance of Dr. Nixon to assist him in a very intricate midwifery case. Dr. Nixon was paid £2 for such assistance, and he (the relieving officer) came before the board to have the payment approved of.

Chairman—Is it usual to allow such a charge?

Relieving Officer—Yes, sir. The law allows two guineas.

Mr. Rowlett asked if there was anything in the fact that Dr. Nixon was their apothecary?

Mayor—Dr. Nixon is our apothecary, but he is fully qualified as a doctor.

Chairman—I suppose I may sign for it?

Mr. O'Connor—The law allows it.

Mr. Sidley—I do not want to oppose payment of this sum, but I consider that Dr. Devany should have been called on in the first instance. He gets £100 a-year as the second dispensary doctor, and he should assist Dr. Laird, and we would not have this additional claim on the rates. On principle, I am opposed to it.

Relieving Officer—On a previous occasion the second dispensary doctor got two guineas for going out of his district in this way.

Mr. Sidley—It is a mistake to say there are two districts in Sligo. Sligo dispensary is divided into two districts for the doctors' own convenience—that is how it is.

Chairman—I think when we are trying to economise the rates something should be done. It is not because we divide a district for the doctors' covenience that we are to pay them extra,

Mr. Sidley—I say that this £2 should never be paid to Dr. Laird. Dr. Laird should have called on Dr. Devany, and if Dr. Devany sent in an application here for £2 we would tell him that we paid him £100 a-year. That is the question, and we should not be going into fragmentary outposts of a district.

The payment of the £2 to Dr. Nixon was confirmed and the matter dropped.

◆

MOUNTMELLICK UNION.

THE CONSUMPTION OF STIMULANTS.

The following explanation was received from Dr. Clarke:

"Sir,—I have to acknowledge the receipt of your note intimating to me the directions of the board of the 12th inst., requiring me to furnish on next board day an explanation as to 'how it is that the use of stimulants appears to have increased the death-rate during the year ending 25th March, 1876, as compared with the 25th March, 1875.' I regret that you did not send me the resolution of the board held on the 12th inst. With regard to the difference in the death-rate of the two years referred to, during my long experience of nearly 26 years there has been always a difference more or less between each year, and as a necessary consequence a difference in the treatment of the patients under my charge, for whom I have endeavoured to prescribe whatever I considered most suitable to their individual cases. I have exercised the strictest supervision and economy consistent with my duty to the poor depending upon me. I beg most respectfully that gentlemen of the board will see the necessity of permitting me to use my discretion in the administration of remedies which I may consider best for the health of those under my medical charge. Should the board consider that there has been any undue expenditure or misapplication or waste of stimulants, I would be most happy to have the matter submitted to the Local Government Board, and an inquiry instituted.

"Joseph Clarke, M.D., Medical Officer,
"Mountmellick Workhouse.

"Dated 19th August, 1876."

Mr. Pattison then proposed, and Mr. A Peacock seconded, the following resolution:—

"That we regard Dr. Clarke's explanation of the matters referred to as quite satisfactory, and that the board desire to express their undiminished confidence in Dr. Clarke's care and discretion in administering to the wants of the patients under his charge."

An amendment was proposed that more detailed explanations be had from Dr. Clarke.

A scene of an unpleasant nature here ensued, in the course of which the proposer threatened to withdraw his amendment if the seconder of it persisted in certain observations. Order having been restored a division was taken, when the amendment was declared lost by a majority of 6 to 2.

ON THE SCIENTIFIC AND EMPIRICAL INVESTIGATION OF EPILEPSIES.

By J. Hughlings Jackson, M.D., F.R.C.P.,

Physician to the Hospital for the Epileptic and Paralysed, and to the London Hospital.

CHAPTER IX.—*Unilaterally beginning Convulsion.*

(*Continued.*)

We shall speak of Range first. We have above admitted that there are all degrees of Range from spasm so local as twitching of one finger to universal convulsion. But we shall make three degrees of Range. They are entirely arbitrary and yet convenient:

1st. The spasm affects the most voluntary muscles of one side—face, arm, and leg. This is the analogue of the first degree of hemiplegia. It will be convenient to call the side first affected the "First Side.' But there is the discrepancy that some muscles of the trunk are convulsed on both sides.

2nd. It affects the most voluntary and other muscles more automatic. This is the analogue of the second degree of hemiplegia.

3rd. It affects all these and the unilateral muscles of the other side of the body (we call this the "Second Side"). This is the analogue of the third degree of, or rather degree of paralysis beyond, hemiplegia.

There are not only three degrees, but also several varieties of hemiplegia. We speak of degrees of that kind of hemiplegia only in which the arm suffers more than the leg; these three degrees from destroying lesions of different degrees of gravity of the corpus striatum correspond to the three degrees of convulsion.

First Degree. (*a*)

Corpus striatum Palsy.	*Corpus striatum Epilepsy.*
Right side of face paralysed.	Mouth drawn to right.
Right arm paralysed.	Right arm convulsed.
Right leg paralysed.	Right leg convulsed.
	Chest fixed on both sides.

The muscles of the chest in this degree of convulsion are involved on both sides, that is, they are involved on both sides when the unilateral muscles are involved but on one side. Yet, in cases of the first degree of hemiplegia, they are not involved. Here is a discrepancy to be carefully considered. (*b*)

The difficulty is cleared by what is known as Broadbent's Hypothesis. Broadbent supposes that the muscles acting bilaterally are represented in each side of even the highest division of the motor tract. Let us take the extreme case of the intercostal muscles to illustrate his hypothesis. He supposes that the nucleus in the cord, for these muscles on one side is united by a commissure with the nucleus for the fellow-muscles of the other side; thus the two nuclei

---

(*a*) I have never, in a case of convulsion affecting one side, made trustworthy observations on the tongue and palate.

(*b*) I use the expressions unilateral and bilateral here for the *action* of the muscles. The muscles of the arm, leg, and some of those of the face can be used independently of their fellows of the other side of the body. Perhaps in strictness we ought to admit that the movements of parts which are most independent in their action are not absolutely so. But, for our present purpose, this would be hypercriticism; they can be used differently from their fellows on the other side. Other muscles, as those of the chest, must move with their fellows of the other side; they are bilateral *in their action* or very nearly so. There are no abrupt demarcations betwixt the two classes of movements. From the most independently unilateral movements of the hand to the necessarily bilateral movements of the chest there are intermediate degrees, as we have remarked.

The expressions "unilateral of one side" and "bilateral of both sides," are not tautological since they are abbreviations of the expressions, "muscles of one side which can act independently of their fellows on the other side," and "muscles which must act with their fellows on the other side."

become in effect a single nucleus—a "unified double," I will call it. By fibres from each corpus striatum to each nucleus, both nuclei are put under the control of each side of the brain. This hypothesis explains satisfactorily how it happens that the intercostal muscles on *both* sides can escape in destroying lesions of one of the corpora striata, notwithstanding that they are or rather were represented in the centre destroyed. Let us suppose that part of the left corpus is destroyed; no palsy of either side of the chest results; this is because the fibres which pass from the other—the right—corpus striatum are intact, and can act not only on their own nucleus in the cord, but by commissural fibres on the twin nucleus. Now let us speak of the *discharge* of the convolutions near to the corpus striatum, practically for our present illustration of a discharge of that centre itself. Broadbent's hypothesis is in entire accord with the fact that the bilateral muscles are put in action on *both* sides. The current from the discharged corpus striatum will discharge the nucleus of its own (opposite) side, and by the commissure the twin nucleus. The discharge will therefore put the intercostal muscles in action on both sides.

There are certain objections to this hypothesis. In the first place it may be denied that the intercostal muscles escape paralysis on the side hemiplegic from destroying lesion of the corpus striatum. To this objection it might be replied that authorities differ as to the fact, so that there is no appeal to them. Nevertheless, I am prepared to grant that in large lesions, and very soon after the attack in small lesions, the chest on that side on which the face, arm, and leg are paralysed may expand less than the other. But it is quite certain that the muscles are but slightly affected—so little, I repeat, that some authorities deny that they suffer at all.

After all the principle of the hypothesis remains intact. Subject to the correction of its distinguished propounder, I would say that its principle is "that the more muscles are bilateral in their action, the more equally are the muscles of both sides represented in each side of the brain." At any rate this is what I think. I have carried the hypothesis further than Broadbent, but, again subject to his approval, I should say that I have added nothing to the principle of that hypothesis. Were it proved that Broadbent's opinion as to the particular mechanism by which bilateral action is ensured is wrong, the principle of his hypothesis would remain.

I have been, from the first moment when I heard Broadbent's hypothesis stated strongly impressed with its great value. I published cases confirmatory of it, *Lancet*, vol. i.—1867 (*The Regional Study of Palsy and Spasm*), and *Medical Times and Gazette*, August 15, 1868 (*Case of Corpus Striatum Epilepsy* (*Hemi-spasm*). (a)

We now come to the second pair of correlated symptoms.

SECOND DEGREE.

A graver lesion of the corpus striatum produces the paralytic symptoms named in the next list, and there is a further degree of convulsion which corresponds. As we are now speaking only of range, as distinct from sequence, we give the symptoms in order from above downwards in the body.

Corpus Striatum Palsy.	*Corpus Striatum Epilepsy.*
Head turns to left.	Head drawn to right.
Two eyes turn to left.	Two eyes drawn to right.
Face turns to left.	Face drawn to right.
Chest muscles slower and weaker.	Chest muscles in spasm.
Trunk muscles weaker on right.	Trunk muscles in spasm on right (?)
Arm and leg paralysed on right.	Arm and leg in spasm on right.

THIRD DEGREE.

In the third degree of unilaterally beginning convulsions the spasm becomes universal. Both sides of the body are affected. I believe that this results from a discharging lesion in but one cerebral hemisphere, as do the first and second degree—that it is the result of a severer discharge. But it will be asked, Where are the paralytic symptoms from destroying lesion on *one* side of the brain which pair off with the spasms of the "second" side in the third degree of convulsions? The spasm after affecting the unilateral muscles of the right side affects next those of the *left*. What in—or of course beyond—hemiplegia corresponds to the spasm of the left, the second, side? There is, I think, a third degree of hemiplegia in which the whole of the muscles of the body are affected. Of course the word *hemi*plegia is now a misnomer; it is a degree of paralysis beyond hemiplegia. The expression beyond hemiplegia is used because the paralysis results from a lesion graver than—but in the same place as—those which produce the first and second degrees of hemiplegia.

Immediately after a very grave (*a*) lesion of one side of the brain there is universal powerlessness. I believe this to be two-sided paralysis. Let us continue to suppose the side of the brain damaged to be the right. It presents no difficulty, of course, that the left side of the body should be paralysed from a right-sided cerebral lesion; but I think the lesion paralyses the other side of the body also—*i.e.*, the unilateral muscles on the side of the cerebral lesion. There is not only a "decussating" paralysis, but also, I think, a "direct" one.

Let us glance at some facts supplied by experimentation on different animals which have different movements. We have seen that in man the bilateral muscles suffer less from a destroying lesion of one side of the brain than do the unilateral, although both are or were represented in the part destroyed. Let us consider the movements of a dog's limbs. The movements of these limbs, even of the anterior, are chiefly alternate, *i.e.*, their action is intermediate betwixt unilateral and bilateral action. He can, it is true, use one fore-leg at a time, but only in a few closely similar motions (although for many purposes). The movements of a dog's limbs approach in character those of the bilateral acting chest muscles in man. Any lesion of *one* side of this animal's brain produces not hemiplegia, but weakness more on one side, but yet of both sides. This shows that in the dog the unilateral muscles of both sides are more nearly equally represented in each side of its brain. Let us now take the case of the bird. This animal's chief movements (of its wings) are quite equal and quite synchronous on the two sides. Here we find that lesion of one cerebral hemisphere produces no one-sided effect. Its chief movements and the representation of them are in the same case as those of

---

(*a*) I think the hypothesis is valuable in many ways. I still think of it as I did (*Medical Times and Gazette*, August 15, 1868), when I wrote "Remarks on Broadbent's Hypothesis:—Broadbent's hypothesis, *mutatis mutandis*, helps us towards a clearer idea of the most general nature of the defects of intellectual expression, and strikingly to the explanation of the involuntary utterances of those patients who cannot speak voluntarily. The fact that patients who cannot speak voluntarily can utter words involuntarily shows that there are sensori-motor processes for words *somewhere* in their brains. And just as "innate" bilateral movements are represented in each of the corpora striata, so acquired processes, when they have become automatic, may also be represented doubly. . . . Moreover, it will be found, I think, that cases of double hemiplegia confirm Broadbent's hypothesis. With regard to this, however, I will content myself by urging those who observe defective bilateral movements with hemiplegia—particularly difficulty in swallowing—to inquire carefully if the patient has not been previously paralysed on the other side. Again, at an autopsy on a patient known to have been paralysed of *but one side*, and who had had difficulty in swallowing, we should search *both* sides of the brain for evidences of disease. For it is a fact that much of the motor tract may be *destroyed* without the production of hemiplegia, or, at all events, without permanent hemiplegia."

(*a*) I use the word "grave" as inclusive of two factors, "(1) extent of lesion and (2) rapidity of lesion." They vary in relative amount in different kinds of pathological changes. This matter will be considered at length later on.

man's most bilateral movements; the wing movements of both sides will be represented equally in each corpus striatum. (a)

When we come to man we should expect that the difference of representation should be carried to an extreme. Thus, except from the gravest one-sided lesions, we do not find that there is any obvious paralysis of the muscles of the second side of the body. Nevertheless, there is proof that the unilateral muscles of both sides are represented in each corpus striatum. The proof is given by cases of Wallerian wasting. Thus, after old lesions of the right corpus striatum, there is "descending wasting" of fibres. We trace wasted fibres through the right crus, right side of pons and medulla, and thence into the *left* side of the cord. All this is simple, and corresponds with the left hemiplegia. But we trace also a band of wasted fibres into the same (the right) side of the cord. Thus, from disease of but one side of the brain, the fact that convulsion, although beginning unilaterally, becomes universal, is in accord with anatomical facts.

We shall have more to say on this when speaking of the sequence of spasm. So far we have spoken only of range of spasm. Under sequence we shall consider the further differences

[We should here speak of aphasia attending epileptic discharges of the centres for speech; but it is convenient to consider it when discussing the After-Effects of strong Epileptic Discharges.]

◆

PATHOLOGICAL ANATOMY OF THE BRAIN—LOCALISATION IN CEREBRAL DISEASE.

By PROF. CHARCOT.

Translated from *Le Progrès Medical.*

CHAPTER V.

BEFORE we more closely enter into the question which serves as the subject of these preliminary lessons (which is, as you have not forgotten, the theory of the localisation of brain diseases), I must give a concluding notice of the considerations presented to you in the last lesson relative to the normal structure of the grey matter of the convolutions studied comparatively in the various regions of the cerebral hemispheres.

A. I must first regard that structure in its common type, that is to say, the form in which it is most generaly distributed. We might, with M. Meynert, describe it under the name of "*stratification in five layers of cellular elements, nerves, or reputed as such.*

I am going briefly to recall to you the traits which are most characteristic of that structure. It is necessary, then, to point your attention again to the figure 6, which represents a section through the third frontal convolution, made to the bottom of a sulcus.

By way of contrast, it will be useful to sketch for you the description of a section of the cerebellar grey matter, borrowed, like the preceding one, from M. Meynert.

In the cortical grey matter of the cerebellum you notice successively—

1. A thick layer, poor in cellular elements, and receiving the proto-plasmic processes of the nerve cells, situated in the subjacent layer.

2. Deeper, a layer where one finds, according to M. Meynert, fusiform cells, and medullary fibres lying parallel to the surface.

3. Underneath Purkinje's cells, occupying the surface of a markedly granular layer, and yet deeper, the medullary matter.

If you now cast a glance at the figure representing the five layers of the grey cortical matter of the brain proper, you will see that the arrangement is not exactly the same as in some other regions of the encephalon.

I shall presently bring out very well-marked distinctions, varying with the region of the hemispheres which we examine, but I must first return to the "five-layered type."

B. The mode of arrangement thus designated is found through the whole extent of the hemisphere in front of the fissure of Rolando, and a little behind it, in one part of the parietal lobes, the limit in the direction of the occipital lobe not being well defined. We shall presently see that this type is notably modified in the posterior parts of the encephalon, comprising (1) the whole sphenoidal lobe, (2) the occipital lobe, (3) those portions of the grey matter of the internal surface, which are bounded by the posterior extremity of the occipital lobe, and by a fissure which marks off a perfectly distinct region, presently to be described under the name of "the square lobe."

But I think it will be necessary, for greater clearness, to return to a point which I have already touched upon, viz., that in the regions of the hemisphere where the five-layered type prevails there is, I repeat, an entire district where the structure of the cortex is remarkable for an interesting feature; one remarks in this locality the constant presence of comparatively enormous pyramidal cells, described as "giant cells." While keeping the pyramidal form proper to the cellular nervous elements of the region, these cells, as you are aware, are distinguished not only by their size, but by the clearness of their nerve prolongations, and by the development of the protoplasmic processes.

These last characters lead us to compare them with the motor nerve cells of the anterior cornua of the spinal cord.

The regions where this important feature is met with are, strictly speaking, the central regions of the external surface of the hemispheres, namely, the ascending frontal convolution, the ascending parietal convolution (especially in their upper parts), and lastly, a little lobule on the inner surface of the hemisphere which until lately has been unnamed, and for which M. Betz has proposed the name, "the paracentral lobule."

I will remind you that the existence of these giant cells in the grey matter, and their localisation in the regions mentioned above were described for the first time by M. Betz and M. Miezerjeweski. The conclusions arrived at by these observers have recently been confirmed by Mr. J. Batty Tuke in his class at Edinburgh. I have, in my turn, been able to recognise their precision.

I have endeavoured to demonstrate to you the fact that these very regions, remarkable for their peculiar structure, are just those in which (according to Ferrier's investigations in monkeys) the motor centres for the limbs are situate. Is not this, gentlemen, a coincidence deserving your careful attention?

(a) The following is an extract from a paper I contributed to the *Med. Times and Gazette*, Oct. 23, 1869:—

"A careful study of cases of disease of the nervous system has led me to conclude that *each* side of the brain contains processes for all classes of movements of *both* sides of the body, but that it contains them differently. The phenomena of hemi-spasm show that the muscles of *both* sides—(1) those which must act bilaterally; (2) those which may act alternately; and (3) those which can act independently—are all represented in *each* side of the brain. But they show also that those muscles of both sides which are in their action bilateral only, are equally represented in each of the two sides of the brain, that the muscles of both sides which are alternate in their action have a less equal representation in each side, and that those muscles of both sides which act independently as well as alternately and bilaterally have a very unequal representation in each of the two sides. The facts supplied by diseases of, and experimentation on, animals seem to show that the representation of the two sides of the body in each side of the brain is more equal the lower we go. These facts, read with the phenomena of hemiplegia, point, I consider, to the conclusion that the units of the nervous system are, like the nervous system itself, double. Using chemical metaphor, the units of Constitution are the atoms, but the developed processes—those which stand out in an actual and in a *quasi-separate* form from the background of potential processes of the whole organism—have a molecular formula containing two atoms. The unit of action is double the unit of constitution."

Instead of saying the "lower we go" [in the scale of animal life], I should now say the more alike are the movements on the two sides of an animal's body.

Let me also revert to the fact that, in the dog, these parts which Ferrier's experiments and Hitzig's previous experiments had shown to be motor centres—these very parts are distinguished, according to M. Betz, by the presence of pyramidal giant cells which are found in no other portion of the grey matter in these animals.

I hope that my insisting on this point is justified by the necessity for fixing these facts on your minds as exactly as possible. Clearly, then, these considerations give a special interest to those parts of the hemisphere where this anatomical peculiarity is met with. I think that it is most important to be well acquainted with these regions topographically, in order to be able to define them precisely in reports of autopsies. I shall, therefore, with your permission, enter carefully into this subject, and it will give us an opportunity for describing the median surfaces of the hemispheres, which have been until now, as I think, left too much in the shade.

The arrangement of the ascending convolutions, from their origin to the upper edge of the hemisphere, is familiar to us, so that we may give all our attention to their appearance on the median surfaces.

Fig. 6.

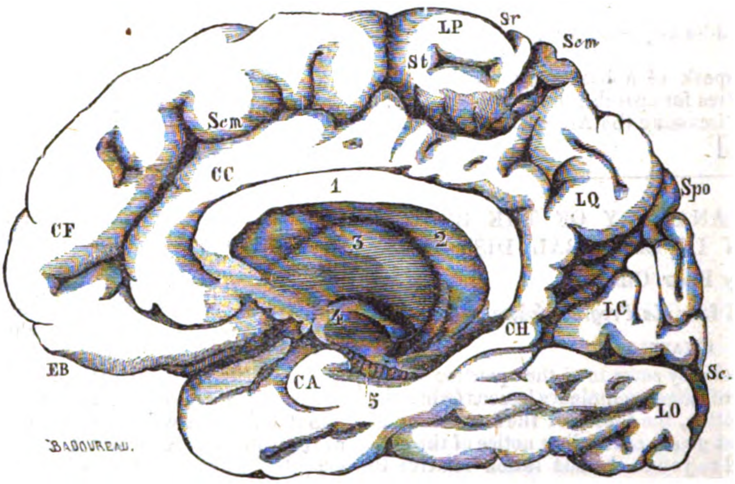

Fig. (6) Internal Surface of the Cerebral Hemisphere.

Sem, Calloso-Marginal Fissure; Spo, Parieto-Occipital Fissure; Sc, Calcarine Fissure; St, Transverse Fissure of the Paracentral Lobe; Sr, Upper Extremity of the Fissure of Rolando; LP, Paracentral Lobule; LQ, the Square Lobe; LC, Cuneiform Lobe; LO, Occipital Lobe; CH, Convolution of the Hippocampus; CA, Convolution of the Cornu of Ammon; CC, Convolution of the Corpus Callosum; CF, Internal Surface of the 1st Frontal Convolution; 1. Corpus Callosum; 2 Cavity of the Lateral Ventricle; 3. Optic Thalamus; 4. Anterior and External Part of the Cerebral Peduncle; 5. the Plaited Body.

In order to set out well, let us take a well-known starting point on the external surface, and follow the fissure of Rolando, going as far as its inner extremity. This fissure sometimes stops *within* the inter-hemispheric fissure; at other times it reaches only to the upper edge of the hemisphere, forming there a kind of notch.

The paracentral lobule is situated directly below this point, and is bounded as follows—*behind*, by an oblique sulcus, which is only the prolongation backwards of the calloso-marginal sulcus (which further on forms the posterior boundary of the ascending parietal convolution); *below*, by the horizontal part of the calloso-marginal sulcus, which separates it from the convolutions of the corpus callosum (gyrus fornicatus); *in front*, a groove, generally of little depth, but sometimes continued over the outer surface of the hemisphere, marks the internal part of the frontal convolution, and thus bounds the paracentral lobule.

We have thus under scrutiny a little lobe of quadrilateral form, having the greater diameter from before backwards. Generally a shallow groove, situated halfway between the upper and lower margins, runs its whole length. To conclude, its structure as well as its relations being considered, we may say that the paracentral lobule represents the inner end of the two ascending convolutions turned inwards toward the middle line.

This point being settled, it is not difficult to show that which remains to be unfolded concerning the topography of the inner surface of the hemispheres. 1. In front of the paracentral lobe you recognise the median (or inner) surface of the first frontal convolution. 2. Underneath, and separated from the last by the calloso-marginal sulcus, is the convolution of the corpus callosum (gyrus fornicatus). 3. This convolution is continuous behind with a well-defined lobule called the quadrilateral lobule. To speak precisely, it belongs to the parietal lobe, forming the median or inner surface of the superior parietal lobule; behind is the temporo-occipital fissure, well-marked in this place because it is not interrupted, as on the outer surface, clearly defining the quadrilateral from the occipital lobe. 4. Immediately behind the square lobe, in the neighbourhood of the occipital, we have to notice a triangular lobule, whose point is below and in front, the base behind and above, bounded behind by a deep fissure ("calcarine fissure"). This little lobule is called "cuneus." 5. Below this triangle you recognise the condition already mentioned regarding the outer surface between the spheroidal and occipital lobes. Here we should make out two convolutions running antero-posteriorly—(*a*) the lateral occipito-sphenoidal or fusiform lobule; (*b*) the median occipito-sphenoidal or lingual lobule. 6. I shall confine myself to mentioning farther forwards the *lobule of the hippocampus* and the *crook* which makes part of the system of the *cornu of Ammon*. We shall assuredly, in the course of these lectures, have occasion to make use of the topographical data which we have just set down, but I hasten to conclude a description which is in some sort a digression.

(*To be continued.*)

◆

The Keighley Guardians, who have made themselves notorious of late by their factious opposition to the Vaccination Acts, were last week summoned for a breach of gaol regulations, in introducing tobacco under cover, and smoking the same within the walls. Three were fined 20s. each, and two others acquitted.

ADDRESS IN PUBLIC MEDICINE.

By Alfred Carpenter, M.D., C.S.S.Camb.

(Continued from page 163.)

It is not assumed that the utilisation of sewage by irrigation is possible in every place. It is, however, simply a matter of cost. At the first sewage conference ever held in this country, which took place at Leamington in 1866, evidence was produced which showed the safety and success of the plan when managed by those who understood it. But the resolution which I submitted to the meeting, and which was ultimately carried without a division, stated that, whilst sewage-irrigation was a method of utilisation which would quite prevent the pollution of our rivers, yet there were places to which it was not applicable, and for which some other means of utilisation must be provided. I wish now to show what can be done by irrigation. The Croydon Sewage Farm at Beddington is at this moment utilising the sewage of 50,000 persons on 460 acres of land. It has been in action for sixteen years, and some of the land has been irrigated more or less night and day for the whole of that time. The farm is close to a dense population; it is immediately surrounded by residential property of the most valuable kind. The efficiency of the soil is becoming greater year by year, as the management of sewaged land is becoming better understood. The population of the parish in which it is situated, and of which it occupies nearly one-fifth of the whole area, has trebled since the farm was first laid out, an increase of population which is greater than has taken place in any neighbouring village or town. The rateable value in the parish books has risen by reason of the increase of building from £11,000 a-year, at which it was rated in 1861, to £36,000 a-year, at which it stands now. The death-rate, which averaged 20 in the 1,000 before the establishment of the farm, has not risen above 17 since it has been in operation. The birth-rate is high, tending to raise the death-rate higher than it otherwise would be. Sewage-farming at Beddington has neither depreciated the value of property nor injured life, but has actually acted in a contrary direction. It has also done much more than that. The land, which was naturally poor before it was taken for sewage utilisation, was let at the agricultural value of 24s. per acre. The neighbouring land has, however, risen in value since then, and now lets at £2 10s. to £3 10s. per acre as market garden land. But the Croydon local board have been obliged to take the land on lease at the enormous rental of £12 per acre, which is rather less than its cost would have been to us if we had purchased it compulsorily. The landlords, instead of receiving £525 *per annum*, now obtain £5,500 a-year without any trouble to themselves; they become rich men, if they were not so before. The farm employs more than three times the number of hands, and raises at least five times the amount of produce. There is at this time upon the farm a herd of nearly one hundred and twenty head of cattle, many of which have been bred on the farm, including fifty milch cows; they are as free from disease and as healthy looking as any herd in any part of the kingdom. Let us bear in mind that the landowners have become rich men, the wages paid have more than trebled, the produce raised has increased by five times; there has been no depreciation of value to neighbouring property, no production of infectious disease or miasmatic influences, but there has been a complete destruction of the contagium-particles which a large population necessarily produces, whilst the effluent water discharged into the river after it has passed over the farm, has seldom been less pure than that supplied to many places as potable water, although I would not, for obvious reasons, be in favour of such water being used for drinking purposes. This result is brought about by continuous movements; from the time the sewage is discharged into the house-drain, until the time when the effluvia leaves the farm, is from six to twelve hours. The most important operation which takes place on a sewage farm is the destruction of contagious particles. The moment they are brought into contact with the spongioles on the rootlets of sewage-grown crops, as may be easily seen in any field of rye-grass which is being irrigated with sewage, the spongioles seize upon the albuminous matters in the sewage by a kind of elective affinity, including the contagium-particles, remove them from the water, and digest them with an avidity which is most remarkable; no putrefaction takes place, no retrocedent decomposition arises, but the albuminous matter is digested as perfectly as white of egg is digested by the human stomach. Putrefaction is no part of sewage utilisation, and if putrefaction takes place, there is a corresponding decrease of productive power, and also a proof that sewage-farming is not properly carried out there. There are three simple rules to be observed. (1) The sewage must be kept near to the surface of the lane, so that the contagium-particles which may be contained therein shall not get beyond the reach of the spongioles of the crop, but shall be digested at once, before they can become reproductive. (2) The amount of produce removed from the land must bear a constant and regular ratio to that of the sewage put upon it; and (3) there must be a rotation of crops, so that the materials common to sewage which one kind of crop does not take out from the 'land may be removed by another class of vegetable produce.

The utilisation of sewage by agriculture is one of the most important actions which the political economist, as well as the sanitary officer, can promote. It is a large field for the investment of superabundant capital, which must bring a handsome return to the inhabitants of the land in which it is invested, even if the investor fails to get a large premium. If one-tenth part of the sum which has been lost in Turkish, Egyptian, Honduras, and other worthless securities, had been invested in sewage utilisation, tens of thousands of acres of land which are now comparatively useless, might be bringing in a yearly revenue of five pounds an acre to the present owners, whilst the produce raised upon them would assist to reduce the famine price of butchers' meat, and be a boon to the country. It is proposed to spend ten or fifteen millions of pounds in the formation of a channel tunnel, which by a slight accident may be entirely lost. A similar sum expended for the purpose of utilising the sewage of London would make 10,000 acres of barren land as fruitful as the Beddington fields, and could not be lost. Motion in contact with atmospheric air in the sewer, on the farm and from the farm, constitute the first principles of sewage utilisation. I say, in contact with atmospheric air, because this is the *sine quâ non* of utilisation. Even in the next best way of dealing with sewage, viz., by intermittent downward filtration, it is an absolute necessity, although in such case the utilisation is secondary and partial only.

Experience has taught us that in dealing with sewage there are two other canon laws which are simple and absolute in their character, and which cannot be departed from without danger. One has reference to the communication between the house and the main sewer. No matter how careful the architect or the sanitary engineer may have been in his plans, the drainage portion of the work is carried out by a class of workmen who habitually slur over their work, and the common laws of hydraulics and pneumatics are studiously ignored. The natural result is occasional or even frequent stoppage. To obviate this danger, no sewer should have any direct communication between it and the interior of the house. Such communication should always be by indirect channels only.

The other canon law is also as absolute. It is, that no water-pipe conveying potable water for use into any house should ever come into direct contact with a sewer or house-drain in any part of its course, especially at the orifice of discharge. The reckless way in which plumbers and house-fitters disobey these laws is producing danger to individuals in all ranks of society. Sewer-air from imperfectly-constructed sewers is laid on to our bed-rooms, dressing-rooms, kitchen departments, and lavatories, as regularly as if it were a necessary of life, whilst the water-pipe is in a thousand instances so placed as to render it perfectly impossible to be used without the contingency of air finding its way to the water from the impurest of impure sources. People reputed to possess common sense do not see the danger of such proceedings, because every one using water liable to be so contaminated is not affected on all occasions and at all times. They argue that the precaution of keeping water-pipes away from the neighbourhood of sewers is unnecessary, because a fatal result does not immediately follow. They might as well argue that a battle-field is not dangerous, because the hero of a hundred fights died a natural death in his own bed.

I am inclined to make seven distinct classes of zymotic disease, and to include among them several which, at present, are assumed to be peculiar to animals alone. But the classification includes all the diseases which appear as epidemics in this country. The conditions are analogous under which one or other of them may arise, according as a concurrence of circumstances come together or not. The first class includes small-pox, cow-pox, chicken-pox, and sheep-pox. Its reproduction requires a germ or atom of potent matter which must be introduced into the animal economy from without. Now and then an individual is found who is insusceptible of the disease. If we could discover the reason for this insusceptibility, we should get the clue to the means which are required for the entire prevention of small-pox, and even render vaccination unnecessary. Attention to ordinary sanitary detail will not prevent its appearance, though it may diminish its fatality. A person who is apparently most healthy, very cleanly in his habits, who always inhales pure air, drinks pure water, and who is but little exposed to the influence of decomposing fæcal evacuations, may yet suffer from the disease. It is true that it is much more fatal in a dark, ill-ventilated house, with the insanitary surroundings which usually belong to such; still the fact remains, that small-pox is not prevented by sanitary regulations alone, and is not so capable of prevention by municipal and personal cleanliness as most of the zymotic class.

A distinguished member of this Association has made out that the milder exanthem, cow-pox, acts as a preventive of the severer form of the disease, simply because it is a modified form of small-pox, modified by its transmission through an animal; the germ which produces it having been a germ of small-pox, changed in its nature by passing through the body of the cow. It is an instance of the way in which Providence places in our hands means whereby we may extract the sting of disease if we set about it in the right way. The recipient of the slighter disease is insusceptible of the severer form of malady for a long time; until most of the tissues of the body have been altogether changed, and new matter laid down in their place.

This insusceptibility to take on a similar form of malady a second time is peculiar to most zymotic diseases. A person having suffered from enteric or scarlet fever, is less liable to suffer from that form of disease again. In this they differ materially from constitutional and functional diseases. If a person have suffered once from gout or bronchitis, he becomes more liable to recurring attacks. He has established a custom which will possibly set up an outlet in his system for the discharge of effete or used-up matter. It has one privilege attached to it; there is often a smaller quantity of the particular material in which the germ or potent matter of zymotic disease delights, that in that person who is apparently in a healthier state, which accounts for the fact that delicate people suffer less severely from epidemic maladies than those who are strong and hearty. The manifestation of zymotic disease represents the result of some potent force or the effect of some living organism acting upon the humours of the body, and altering the condition of the system, which requires years to efface. It removes from the system the whole of the matter in which the active principle of infectious disease can revel; and until production of its particular pabulum takes place that particular disease cannot arise again, because there is no food for the active principle to live upon. I much doubt if this potent force or living organism, take it as we please, could have any effect upon the body, if the recipient were perfectly healthy; if no impunity existed in the fluids of the body; if the blood contained nothing foreign to a healthy and natural state. If this be so, a question arises, as to whence these impurities proceed, and how their effects are to be guarded against. I venture to put forth an hypothesis for consideration, which will explain much which is difficult to understand on any other view. Some impurities must exist; they are the used-up matter, the result of the act of life, or they may be inherited tendencies, which have resulted from former neglect of sanitary law, and which have depreciated the quality of the stock, and rendered it more susceptible to bad influences. The impurities naturally increase if there are any defects in the sanitary arrangement of the individual corpus. Their presence is of no moment if they are not in excess, and if they are removed from the body as fast as they are formed, or in the course which they naturally follow. Let us represent them by X, in an equation in which the factors X, Y, Z (as a total) represent any form of epidemic disease. The problem is to assess the value of each factor in the equation. Divide the factors with two parts: centric elements, or those which are proper to the body; and eccentric, or those which act upon it from without; X, Y, Z, may equal zymotic disease of any kind. Let $X = U$ and E; U being the used-up material, the formed material of Beale, always in the act of formation, is not foreign matter and is not in ordinary proportions injurious to life. It is always being diminished as fast as it is formed, by one or other of the excretory organs which exist for the purpose of removing it. If all the excretory organs and all functions be healthy, and all doing their work properly, the body is in good health, there is no excess of used-up material, no *débris* of combustion. If, however, one or other of the excretory organs fail to do its duty, from either overwork or inertness, something is left in the humoral system, and E is added. It becomes a positive quantity, and represents the excess of matter which should have been removed, $U + E = X$. They have a common origin, being the *débris* of the act of living; E will differ in quantity as well as in quality. It will be modified by personal character, by actions, by non-actions, and even by attainments, but especially by attention to or neglect of sanitary and moral laws. Still more will it vary according to the circumstances of the community among whom the person resides, the moral and the sanitary state, or the habitual neglect of sanitary law in which that community may indulge. Thus, a municipal authority who allows over-crowding, foul air, immoral acts on the part of the people, impure water, or bad food, is providing an excess of E, and increasing the danger which may arise from the introduction of the potent principle of infectious disease. If E be absent, X is not complete, and X, Y, Z cannot arise; X even may be complete from the circumstances I have detailed, but Y, Z, are still required to establish an epidemic. If Z be made to correspond to an atom of potent matter, a germ or living organism, the particular contagium of any kind of zymotic disease, the multiplying focus of infectious disorder, and one of the eccentric elements in the equation, it has to be introduced from without, and is capable of modification according to the character of the soil into which it may happen to be transplanted. Like the torula cerevisiæ or the Penicillium glaucum, upon which fermentation depends, and without which alcohol is not produced if Z do not gain admission to some part of the humoral system, the entity, zymotic disease, cannot arise. Just as Penicillium glaucum requires the sugar and the temperature to produce alcohol, so Z, the contagium-particle, requires the food upon which it increases and multiplies, as well as certain meteorological states for its proper development. These latter conditions are represented by Y. The severity of the disease will depend upon the quantity of E which exists in the factor X. The epidemic will be more or less general and fatal, according to the greater or lesser quantity of E in each individual, not according to the character of Z; Z will be reproduced according to the quantity of food in the recipient upon which it can increase and multiply. If E be absent, the effect of Z will be nothing, for there is nothing for it to feed upon. If, therefore, personal cleanliness be attended to, if all the excretory organs of the body be properly exercised, if the municipal authority have insisted upon obedience to sanitary law, if moral laws be obeyed in each unit of sanitary work, the effect of Z, whenever it happens to be introduced, will be reduced to a minimum, and Z may be so dwarfed as to be unable to effect a lodgment, or it may die out entirely. It will be by directing attention to the necessity of diminishing the growth of E that we shall prevent epidemics from spreading, rather than by useless attempts to keep out Z; by correct sanitary administration, rather than by trying to establish an all but impossible quarantine. If E in the factor X abound, and quarantine be not effectual, if Z once pass through the cordon, the power of the latter is lost, and all our work in that direction has come to nought. The equation stands thus: $X = U + E$, and represents the used-up material, the result of the act of life; $Y =$ the meteorological conditions, such as temperature, moisture, and certain atmospheric states which are required for the rapid increase of epidemics; $Z =$ the contagium-particle upon which the nature of the disease depends. The fatality of the disease will depend upon the quantity of E in the factor X. The rapidity of growth will depend upon certain meteorological states represented by Y, but the character of the disease itself will depend upon Z. We can diminish X to a minimum by personal, municipal, and sanitary arrangements; we cannot alter Y, but we can impede the introduction of Z, and prevent epidemic disease, unless it can be shown that zymotic diseases may arise *suâ sponte*. As regards small-pox, there is not any difference of opinion on this point. It certainly requires the introduction of Z from without, and if the contagium-particle be absent, small-pox cannot arise. It has been clearly shown that the contagium-particle is a living organism requiring certain forms of matter for its development, and if it do not meet with that matter its character is altered, and it is no longer the same entity.

There is a class which includes measles, whooping-cough, influenza, catarrh, and eczema epizooticum, in which Z appears to be a germ of living organic matter, most probably of vegetable origin, possibly the fructification of a class of organisms which have recently been called schizomycetous, and which are too minute for separate identification with present microscopical powers. That vegetable matter can produce similar effects, is seen in the action of the pollen of anthoxanthum odoratum, and also of the fine powder of ipecacuanha. The effect of these reagents upon the mucous membrane is not constant, it only arises in some persons. Year by year we find the persons affected to be more numerous. They probably have E in the factor X, in some form or other in their systems. The action produced is immediate, and it may be likened to that set up by mustard. The latter affects every one alike, in which it differs from hay-asthma. The action produced by fungi is not immediate; there is a period of incubation, a period sufficiently long for the production of an immense multiplication of fungus-growth, and, as a sequence to that growth, the production of a chemical result. Growing fungi produce carbonic acid or other acid or etherial products; there is always a considerable formation of gaseous matter produced by such growth. This can set up irritation in the tissues, just as formic acid can, if injected under the skin. The germination, and, as a sequence, the multiplication of fungi in acid media, is one of the wheels within wheels often met with in nature, where reproduction is more rapid, because reproduction itself produces material which increases growth. There is a marked difference between the effect of the materies morbi which sets up epidemic catarrh and that of pollen upon mucous membrane. The one is reproductive, the other is not. It is in the result of reproduction that the cause for the catarrh is to be found. In that reproduction, a material is set free which acts in a manner similar to the pollen of the anthoxanthum. Those who live in close ill-ventilated rooms, and who object to admit fresh air, are said to take cold when they do so. It is not the fresh air which injures them, but it brings into contact with the patient's mucous membrane some germ from without, or else it disturbs some such in the ordinarily undisturbed part of the room. The fruit takes root and grows in its new home, reproducing itself, perhaps, like cow-pox, under altered conditions, and in that reproduction sets free a material which is the actual cause of the catarrh.

The effect of copaiva in producing a rash similar to, and which cannot always be distinguished from, measles, except by the absence of fever, is a proof that a vegetable product can excite a similar state. It has not been shown that the rubeoloid eruption which sometimes follows the use of copaiva has any protective influence against true measles. An extended series of observations are required to prove this point; and it may be that there is an opening for information which is worth following up. Measles is more generally prevalent in mild damp seasons: it always appears more or less about cleaning time, when old heaps of rubbish are being disturbed, and decaying organic matter from homesteads and farm-yards are being spread over the soil. It appears then as an epidemic, as if there were a sequence in the operation. It is possible that the schizomycetous organisms may be altered forms of some particular mould or smut, altered in the character of their fructification, and altered in their mode of growth by transplantation to a new home; just as the contagium-particle of small-pox is altered by its transit through the humours of the cow. Alterations of this kind do occur: the connection between the echinococcus and the tape-worm is a case in point; and it does not follow that the organisms themselves are distinct species which require a continuous existence in that form for their occasional appearance as epidemics. Just as with small-pox, some persons never have measles, or whooping-cough, or scarlatina, though frequently exposed to the influence of the contagion. Whoever discovers the cause of this exemption will confer a boon upon humanity, as in that discovery will follow the establishment of a means for preventing altogether that class of disease.

The class which includes diarrhœa, cholera, dysentery, enteric and intermittent fever, is essentially one of filth-disease, arising from the effects of a sewaged soaked soil, of polluted water or air, rendered foul by miasms from decomposing organic matter. Wherever any of this class put in an occasional appearance diarrhœa is certain to be a regular visitor whenever the temperature rises above the ordinary standard, and continues high for any time. It has been imputed to the rise and fall of the water-line in the subsoil in connection with the rainfall of the district. A close investigation of the conditions under which summer diarrhœa arises in those towns in which it is prevalent—such as London, Leicester, and Berlin—shows conclusively that, although the highest mortality corresponds with the lowest level of ground-water, there is no relative proportion in any other point. A relation does exist between the origin of the disease and heat. The greater the heat the greater the mortality; the lower the amount of moisture in the air, the higher the death-rate from diarrhœa. A fall in the death-rate follows upon the return of atmospheric saturation. The fall in the level of ground-water, the increase of temperature, and the diminution of water in the air all occur together. Then it is that those who inhabit cellars, underground dwellings, dark, ill-ventilated houses, houses in which dry rot is taking place, all places likely to get an excess of carbonic acid in the air, suffer from the disease. Hand-fed children suffer first and most heavily. This appears to prove that the food is the main starting point. The food, when given, is about to undergo some change promoted by living organisms, which flourish most luxuriantly under the conditions mentioned. They obtain a lodgement in the mucous membrane of the alimentary canal, and destroy the child by destroying the nourishing properties of the food exhibited. Pettenkofer thinks that locality has more to do with the disease than the introduction of any particular germ—that removal from the place will prevent or even cure the disease. He imputes it to some influence produced on the people by the rise and fall of water in the subsoil. This rise and fall of water is connected, but it is as a coincidence. The conditions which give rise to infantile diarrhœa are those which promote the growth of certain living organisms. Such growth takes place most rapidly at high temperatures, when evaporation is rapid, and when the underground air has an excess of carbonic acids in its composition, together with the organisms which accompany that excess—conditions which are likely to be in association with a low water-line, conditions which are always followed by heavy rainfalls. The z in the equation X Y Z = infantile diarrhœa is some living organism developed by continuous heat, by dry air, excess of carbonic acid in that air, and some other unknown condition. This organism finds admission into the stomach with the food, sets up a fermentation by which the nourishing power of the food is destroyed; produces an irritating material, which, uniting with X, causes prostration; and if this be not fatal, the child is starved to death. The localities in which diarrhœa arises are the favoured haunts of cholera and enteric fever under other meteorological states in which heat and dryness are not contingencies. Pettenkofer considers their origin to be due to local and personal considerations, and believes that quarantine is useless. The conditions which herald the approach of cholera are progressive from place to place. The factor X may be brought in, and the disease produced earlier than it otherwise would if it had to wait for development *suâ sponte.* The observations of Dr. Klein have established the coincidence of living organisms and typhoid in a way which is beyond cavil. In solving the power of each member of the equation X Y Z = enteric fever, we may be certain that the factor Z is a living organism capable of reproducing its like in any situation in which fæcal contamination has occurred, and in which the products of filth-decomposition are to be found.

Do any of these diseases arise *suâ sponte?* The sudden way in which some of them develope sanctions the idea. This is especially the case with enteric fever and scarlatina. Many intelligent and accurate observers have been unable otherwise to account for the appearance of those diseases in given cases. Yet the ordinary laws of natural history would forbid the suggestion. Growths, apparently spontaneous, are common in the vegetable kingdom, but in no case is it supposed that the growth has taken place without the previous presence of appropriate spores or seeds. The sudden and wide-spread appearance of eczema epizooticum among cattle, or the destruction of potato by potato-blight, seem to be spontaneous, yet those diseases spread by contagium-particles; we may reasonably suppose that the propagation depends upon spores like to Penicillium glaucum or mucor mucedo. Those spores are to be always found, only waiting for a suitable situation to grow and become fertile in a few hours. They are both aerial and aquatic, and produce different results, according to the dryness or moisture of the position in which they are found, and are modified by the acidity or the alkalinity of the media in which they multiply. Bacteria of different kinds are found in one, vibrios in another; why should not those forms produce a potent matter in their growth, capable in itself of producing disease? We know that certain kinds of fish may be eaten to-day with impunity, but to-morrow they set up serious disturbances in the animal economy. Vibrios to-day may be harmless, but to-morrow they may produce disease. The secretion from the peritoneum to-day may do no mischief; to-morrow an irritative action may arise which will set up a most virulent and infectious complaint. In peritonitis, a most fatal form of infective disease may be set up, and the infectivity arises *suâ sponte,* because certain circumstances have been altered, and the bioplasm, existing normally in the tissues, has taken on a new action. The germs were there, but, the vital conditions being altered, a comparatively harmless secretion is turned into a virulent poison.

I believe this to be the case with those specific forms of contagion which are multiplied by filth. Scarlatina and typhus, enteric fever and cholera, arise apparently *suâ sponte,* because certain germs or foci of potent matter have been altered by the circumstances in which they are placed, and infective power has been added, just as infectivity is produced in the peritoneal secretion by inflaming the membrane which secretes it. The ordinary excreta of carnivorous animals, which contain the *débris* of animal food may or may not be so placed as to produce the germ upon which filth-disease depends, just as dry rot may or may not arise in a building, according as to whether ventilation has been provided for and new wood kept out of the fabric. But if these germs be introduced into the human economy, the disease arises and spreads in the usual manner. So again with scarlatina, long-continued observation and analogy forbids the idea of an origin, except from some bioplasm finding a suitable soil in which it may develope its poisonous character.

Time fails me to go through the list of zymotic diseases, and show the character of Z in each class. There is a close analogy, a continuing alliance, and a similar explanation can be made as to the value of Z in each member of the class.

Zymotic disease, in the majority of instances, has its power of producing evil more in the character of the recipient than in the quality of Z. Obedience to sanitary law in private life, together with the performance of public duty by local authority will give comparative immunity from epidemic and infectious diseases, and render us in a great measure independent of the trammels of imperfect quarantine.

As zymotic disease has its main impetus in the disregard of duty, those who advocate the performance of that duty must be prepared to encounter opposition and witness an ebb-tide in sanitary work. It is imperfect knowledge on our part which gives strength to the opposition. It is our duty to persevere in the prosecution of a more perfect work. Motion, as opposed to stagnation, simplicity, as opposed to complexity, should be our cardinal points; and if to this we add the peremptory utilisation of animal *débris,* the sting of epidemic and infectious disease will be taken away, and, in the words of the Psalmist, "we need not be afraid of the pestilence which walketh in darkness, nor of the destruction which wasteth at noon-day."

It is our duty to strive to reach this point of perfection. It can be obtained only by educating the people as well as ourselves aright, and we must trust to Providence for our reward.

Clinical Records.

JERVIS-STREET HOSPITAL, DUBLIN.

OPERATION CASES UNDER THE CARE OF DR. MELDON.

CASES OF BLOODLESS AMPUTATION OF THE LOWER EXTREMITY.

Excision of the Os Calcis and Subsequent Amputation.

(Reported by Mr. RICHARD HUGHES, Resident.)

FANNY CHURCH, a delicate girl of 19 years of age, was admitted into Jervis-Street Hospital on the 21st May, 1874. The previous history showed that she had never been very strong, and that some eight years ago she had been under treatment and operated on for necrosis of the tibia. For two years after this date she improved slightly in health, but during the past six years she has been gradually losing strength. Of late, abscesses have formed rapidly in almost every part of leg and lower part of thigh. Her appetite too has become so bad that she can take little or no nourishment, and severe startings of the leg have rendered her nights almost sleepless.

On admission she was found very much emaciated, perspiring profusely, and suffering much from starting pains in the foot and leg. Discharging sinuses were to be found in every part of the leg, foot, and lower part of the thigh. This, added to the fact that there was tubercular deposit in the left lung, accompanied by all the symptoms of hectic fever, rendered the case all but hopeless.

The morning after admission the limb was carefully examined by Dr. Meldon. The only part wherein the diseased bone could be detected was the os calcis, and in many places this bone was found bare and rough. To relieve her from the great suffering it was proposed to amputate the limb. To this, however, she would not submit. It was then resolved to excise the calcaneum. After some preparatory treatment a T-incision was made over the diseased structure, Esmarch's bandage having been previously applied. As much of the bone as possible was then exposed by dissection, and being found completely softened it was divided with Dr. Stapleton's powerful pliers; the remainder portion was gouged out.

For some weeks after the operation the patient improved very much; her appetite returned; the starting pain had completely ceased, and every hope was entertained that the operation would be successful; but suppuration soon began to tell on her enfeebled constitution, and to save life it became necessary to amputate her leg. This was done by Dr. Meldon just five weeks after the excision. The operation, like the former, was done bloodlessly, and to this Dr. Meldon attributed the rapid recovery she made, leaving the hospital just three weeks later (31st July, 1874) with the stump quite healed, and having increased in weight.

June, 1876.—Fanny Church was examined this month and found to have lost all traces of phthisis, and has since her discharge from hospital been in perfect health, and has been able to do a great deal of hard work, having already worn out one artificial leg.

Bloodless Amputation of the Thigh.

(Reported by Mr. CHARLES ENNIS.)

Mary Ann Haynes, a married woman, aged 34 years, was admitted into Jervis-Street Hospital on the 27th of October, 1873. For some time previously she had suffered from severe pain in the ankle-joint. Lately the leg has become much swollen and inflamed.

The day after admission she was examined by Dr. Meldon, who made free incisions into the leg, from which much bloody matter escaped. For some time she was relieved, but prolonged suppuration reduced her to such an extent that to save her life it was determined to amputate the leg.

At the date of the operation she was so weak that it was not without danger she was removed from her bed to the operation table. Esmarch's bandage was applied, and Dr. Meldon removed the leg through the lower third without the loss of a single drop of blood. From the date of the operation she improved rapidly, and left the hospital three weeks later with the stump healed. Her rapid recovery Dr. Meldon stated he believed to be due in a large degree to the fact that she had lost no blood.

Case of Bloodless Amputation of the Thigh in a Patient far advanced in Phthisis.

(Reported by Mr. THOMAS E. WHITE.)

John Keane, aged 25, was admitted into Jervis-Street Hospital in the middle of August, 1873. At the time of his admission he represented as marked a case of scrofula as could possibly be seen. He had lately been discharged from Mercer's Hospital, where the middle finger of his left hand had been removed for caries of the metacarpal bone. Anchylosis showed that the right knee had shared in the general condition. There was likewise extensive tubercular disease already far advanced in both lungs, and the whole length of the left leg, from the tuberosity of the tibiæ to the tarsus, presented at variable intervals, sinuses leading to diseased bone. Hopeless as the case seemed to be, at the patient's urgent request Dr. Meldon consented to amputate. On the 10th of September the operation was bloodlessly performed through the lower third of the thigh. For three days after the operation he improved very much in health; but on the morning of the 13th he became restless, after having struck the stump violently against the cradle which was protecting it. A second afterwards it was found that the stump was bleeding. Fortunately Dr. Meldon was in the ward at the time, and at once succeeded in arresting the hæmorrhage. Notwithstanding this check in his recovery, he improved gradually until the 24th, when the stump was healed. A short time after this he left the hospital much improved in health.

Bloodless Amputation of the Leg.

(Reported by Mr. THOMAS E. WHITE.)

Julia Leckey, aged 11 years, who had been attending the hospital dispensary for some twelve months, was admitted into Jervis-Street Hospital on the 13th September, 1875, with strumous disease of the tarsal bone, ankle-joint, and lower portion of tibia and fibula.

A few days after admission Dr. Meldon amputated the leg, having previously applied Esmarch's elastic bandage. After this she made a rapid recovery, and were it not that one of the ligatures remained for some time longer than usual, she would have been fit to leave the hospital fourteen days after the operation.

Dr. Meldon, in his remarks to the student, mentioned that some surgeons objected to use the elastic bandage in amputations where there was much suppuration in the knee or leg; but the cases in which he has used it within the past few months clearly showed the students that its use was most serviceable instead of being objectionable.

Obituary.

DR. LUTHER, OF CAPPOQUIN.

WE announce with regret the unexpected death of this estimable gentleman, whose contributions to our columns of excerpts from the foreign medical literature of the day are well known to our readers. In the locality in which Dr. Luther lived and practised he was universally esteemed, and is now regretted in remembrance of his skill as a surgeon and physician. He was carried off by an attack of gout in the stomach, at the early age of 39.

◆

SIMON NICOLLS, M.D., OF LONGFORD.

DR. NICOLLS died of apoplexy at an advanced age in Longford on the 27th ult. The attack to which he succumbed was induced by exposure to cold during the erection (on the 26th ult.) of a dam for sanitary purposes. He was an M.D. of Glasgow, and a licentiate of the Edinburgh College of Surgeons, and for the past twenty-six years filled the post of medical officer to the Longford Workhouse. He enjoyed a lucrative obstetric and medical practice in Longford and the adjoining counties, which he never relinquished, and it may be truly said "he died in harness." The cause of temperance ever received his warmest and most persevering support, he being a strict teetotaller to the day of his death. His essay on "Protracted Labour" (communicated to the Dublin Obstetrical Society, 1875-76) was a valuable contribution to obstetric literature. He was genial, hospitable, witty, but not in the least sarcastic, firm and consistent in his religious and political views, was equally tolerant to all who differed from him. His efforts in the cause of charity may be said to have had no limit. By his death the poor have lost an ever ready friend in need, the public service a valued officer, and medicine a devoted disciple and indefatigable worker.

REGISTERED FOR TRANSMISSION ABROAD.

THE
MEDICAL PRESS AND CIRCULAR
is published every Wednesday morning. Price 5d. Post free, 5½d.

POST FREE TO ANNUAL SUBSCRIBERS £1 2 6
„ IF PAID IN ADVANCE 1 1 0

⁂ Post-office Orders and Cheques to be drawn in favour of—
A. A. TINDALL, 20 King William Street, Strand, London, W.C.
A. H. JACOB, 23 Ely Place, Dublin.
MACLACHLAN and STEWART, South Bridge, Edinburgh.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIERE, Rue Hautefeuille, Paris—post free in advance, £1 5s. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLMER and ROGERS; Baltimore, by Messrs. KELLY and PIET; Philadelphia, at the *Medical and Surgical Reporter* Office, post free in advance, £1 5s., about six and a-half dollars; or direct from the Offices in this country for the same amount, by International Post-office Order.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 6, 1876.

LEGISLATIVE RESTRICTIONS FOR HABITUAL DRUNKARDS.

VERY recently we drew attention to the report of the British Medical Association on the advisability of legislative restrictions for habitual drunkards, as well as to the petition which their Committee has prepared for signature by members of the profession, as well as by the general public. That this movement on the part of the Association is one which involves much careful consideration, and on the propriety of which there will be a great difference of opinion both in and outside the profession, is evident from the short discussion on the report which took place at the third general meeting of the Association, and which we will briefly notice before we proceed to make any remarks of our own.

Dr. Carpenter, in moving the adoption of the report, dwelt upon the importance of the objects they had in view, and urged that the petitions should be extensively circulated amongst those who take an interest in the matter, and when filled up, placed in the hands of members of Parliament early next session. Dr. Chadwick seconded the motion, with the remark that he had no doubt all present were agreed upon the matter. On the other hand, Dr. Bucknill entirely objected to the proposed petition. He denied that the power of compulsory committal and detention of drunkards was, as had been stated, legally in operation in various parts of the United States. The Supreme Court of that country had ruled that drunkenness was not an offence, and that the New York Legislature had no right to pass such a law as that to which reference had been made. He objected to the term "not exceeding one year," as not affording sufficient time for the reclamation of drunkards; he questioned the correctness of the statement that a large percentage of habitual drunkards had been reclaimed; and he also disagreed with the assertion that penal legislation with regard to them "is worse than useless." Lastly, he said that although a case had been made out against habitual drunkards among the working classes in this country, the Association proposed to legislate for a superior class against whom no case had been made out, and he did not believe there was the slightest probability of passing such a law through the legislature of this country at the present time. The next speaker, Dr. Morris, warned the Association against lending itself to any legislative "measure for muzzling any section of the community," and said it was quite beyond their function to attempt any such thing. Another gentleman, Mr. Watkin Williams, defended the motion. He said that their object was not "imprisonment," but "amendment," to cure inebriates and not to punish them, and that they, as an association of medical men, could have no better object in view, particularly as one of their great objects was to cure all disease to which the human kind was subject; and with regard to the duration of confinement, he said he would rather see the head of the family confined for two or three years, or even for life, "than be a disgrace to her husband and children, and the laughing stock of her servants." In reply, Dr. Carpenter satisfactorily met the objections that Dr. Bucknill had made, and asserted that the latter physician had misunderstood the object of the petition, and had totally misrepresented it. With regard to the influence of short terms of imprisonment, the evidence given before the Select Committee which sat in 1872 showed that it was true. "As a magistrate in the south of London, he had to hear these cases day by day, and had to commit these poor drunkards over and over again, knowing that as soon as ever they came out of prison they would be before the Bench again. He had no hesitation in saying that in such cases short terms of imprisonment were worse than useless, and that to treat habitual drunkards in such a way was a great mistake. He never sent a person to prison in that way without feeling that he was doing an injustice in punishing as a crime that which, in reality, was a disease. They had no more right to send these poor people to the treadmill for a fortnight for getting drunk than they had to send them to a lunatic asylum. The treatment required was not penal, but curative; and that was the great object for that Association to promote."

Such are some of the first steps in a movement, the results of which may be of far greater consequence to the future well-being of society than is generally supposed. Whatever may be thought of the advisability of placing habitual drunkards under legal restraint, no one can deny that it is a question in the discussion of which the medical profession or any of its representative associations is particularly concerned, and in the final settlement of which it is entitled to a most respectful hearing. The object of this proposed legislation is for the benefit of the individual, of his family, and of society at large, and no body of men could with better grace suggest the best means of carrying out so praiseworthy an object as those who are so continually coming in contact with the social evil complained of, and with the mischievous results of which they have in their professional capacity so frequently to deal.

But with regard to the question itself, the propriety of legislative interference, there are, in our opinion, three great points for consideration—first, whether the evil exists to such an alarming extent as to call for restrictive measures of an extraordinary nature; secondly, whether the object in view could be gained by any other means; and, thirdly, whether the proposed scheme is really practicable. That habitual drunkenness exists among the poorer classes of this country to such an extent as to call for some kind of interference on the part of the Government is generally admitted, even by those who, like Dr. Bucknill, think that no case has been made out against the upper classes of society. Had Dr. Bucknill, however, practised as a general physician, or as a general practitioner, we feel sure he would have formed a very different opinion. There is, perhaps, not a medical man in practice who is not often meeting with ladies and gentlemen who are habitual drunkards, whose homes are, in consequence thereof, made wretched and almost insupportable, and in whom there is not, while they have their liberty, the least chance of any reformation. As Dr. Carpenter justly observes, private drinking had during the last few years greatly increased in the middle and upper ranks of life. Only recently it has been our lot to witness in two ladies, each the mother of several children, the most deplorable intemperance—intemperance which had been going on for years, which all devices, all threats, and all persuasion had failed to cure, and which completely jeopardised both the physical and moral training of the children, and eventually broke up what might have been prosperous and happy homes. That the percentage of habitual drunkards is very much smaller among the higher than among the lowest orders of society we will readily admit; but if the case made out against the middle and higher classes is not so strong as that made out against the working classes, it is to be borne in mind that the grief and misery attending upon this evil, and the want of some public reformatory to which the unfortunate individual may be legally consigned, are felt far more poignantly in one case than in the other, while the chances of a successful and permanent cure are certainly greater among the former than among the latter class. That such is the case is evident from the fact that it is not the sottish and wilful drunkenness among the lower orders of society which has made so many medical men and so many affectionate fathers and mothers wish that there was some such asylum as is now proposed, but those less repulsive and irresistible forms of intemperance which are unfortunately so prevalent in the higher ranks of the community.

For these and other reasons into which we cannot now enter, we may take it for granted that habitual drunkenness does exist among all classes to such an extent as to necessitate some better check being put upon it, and some better plan of treatment adopted than that now pursued. But it may be worth while to consider whether any other means might be resorted to than that of calling in the aid of legislative restrictions.

We have used the expression, "habitual drunkenness," for the sake of convenience, and as a general term applicable to all who give way to habits of intemperance; but we must bear in mind that we have to deal with two very different classes of cases, of which one may be said to be best represented by the drunken navvy, the other by the genteel dipsomaniac. With respect to the former class of people, who attract most attention in consequence of the brutal assaults with which their habitual drunkenness is so frequently associated, some hopes have been entertained that short terms of imprisonment would have a deterrent effect upon their drunken habits, until the time arrived when the improved condition and education of the working classes rendered such punishment unnecessary by removing the causes which gave rise to them. Short terms of imprisonment have been found to be a failure, nor must we be too sanguine as to the good results which are expected to follow from the general education and elevation of the masses. Dr. Carpenter is not the only magistrate who has repeatedly had to commit the poor drunkard to prison, in the full assurance that as soon as he came out of prison he would come before the Bench again. Nor could we expect otherwise. Short terms of imprisonment are just sufficient to make the prisoner miss his customary stimulants, and to induce him, on gaining his liberty, to rush to his liquor with tenfold more zest than before, without having afforded sufficient time to completely break him of his habits, and for his brain to get into such a healthy state, and his propensities to be so thoroughly subdued as to enable him to steadfastly resist the temptations to which he may be exposed.

With regard to that form of habitual intemperance which exists among the middle and higher ranks of life, no attempts have hitherto been made to grapple with it. The infatuated woman may have been for years a curse to her family, but she is never found drunk in the streets. She seldom commits any felony or assault: consequently, she never renders herself liable to any penal imprisonment, useless though it may be, but is permitted to have full liberty to go her own course, until some disease, the fruits of her intemperate habits, has put an end to her miserable existence. That in these sad cases there is nothing to be done short of either some such legislative restrictions as those now proposed, or letting things remain as they are, is so evident to all who have had anything to do with this unfortunate class of people, that we need not dwell upon this part of our subject any longer. On another occasion we shall consider the advantages that may be reasonably expected from the establishment of reformatories to which the habitual drunkard may be legally consigned, and inquire how far such a scheme is really practicable. In the meantime we hope that the present movement will receive the support of both the profession and the public, and that the number of signatures attached to the petition will show that any action the Government may think proper to take in the matter will be in accordance with the wishes of all classes of the community.

PROPAGATION OF SCARLATINA FROM MILK.

Dr. Buchanan has lately brought out his report on an outbreak of scarlatina which occurred some time since in South Kensington, and which had been apparently propagated by milk. The outbreak took place on the 9th of June, 1875, in a family living in the above neighbourhood, as well as among some guests who had assembled at the house. Among these people, numbering about 180 persons, there occurred between the 11th and 14th of June the following cases of scarlet fever and sore-throat, supposed to have been of a scarlatinous nature:—Of the family, four out of seven were attacked with scarlatina; of the servants, three out of seven; of the dinner guests, six out of twelve; of the evening guests, only (so far as known) four, and one of the occasional servants. Hence, within five days of June 9th, eighteen individuals were affected, but it is right to state that six of these had sore-throat only, and in all the others, except one, the attack was very slight, and in one or two cases, doubtful. The diagnosis of the disease rests with the seven medical men who attended upon the marked cases. "Beyond those originally attacked," observes Dr. Buchanan, "the disease did not spread, except in the form of feverish sore-throat to persons in communication with the patients." The peculiar nature of the circumstances attending this outbreak suggested that the infection of scarlet fever had been contracted by the persons affected, at the same time, and from one and the same source, namely, at the assembly on the 9th of June. No direct source of infection was ascertained, either in the household itself or among the guests; but after various inquiries, the question was at last limited to the possibility of infection having been propagated by some of the food that was used during the evening above mentioned, probably the cream. It appears that, besides an extra quantity of milk supplied in the ordinary way, a store of cream was taken in from two different sources, one supply (at four o'clock) coming exceptionally from a London dairy, kept by Mr. M., while the five o'clock cream had been supplied by the ordinary milkman from milk that had travelled up from Hampshire. Moreover, according to the cook's account, the general cream supply of the day was from the Hampshire dairy, and it was this cream that was partaken of by a large number of evening guests without any results. But the distinctively dinner supply was from Mr. M.'s, London dairy. It was this cream which was distributed essentially to the family, to the dinner guests, as well as to four ladies of the family and a guest, who had partaken on the next day of certain dishes that had come untouched from the dinner table. Now it was among these people, including the ladies just mentioned, that scarlatina was distributed, but the disease did not affect generally the evening guests, who had almost wholly partaken of the five o'clock supply from the Hampshire dairy. "It is thus seen that the four o'clock cream and the scarlatina went in the main together, though there were exceptions which obviously required, and promise to reward, more particular study." We may therefore conclude "that of those of the family and dinner guest who were afterwards taken ill all had partaken of cream in one form or other, while of those who were not taken ill, a majority had not used cream in any form." . . . "The earlier evidence showed a considerable probability that the disease was spread by some article of food or drink, and the present evidence shows that the particular article may not improbably have been the cream supplied to the house at 4 'o'clock on the day of the party."

The above is but a brief *résumé* of this interesting report in which several other questions are raised than those we have been able to notice. The report itself, however, will amply repay perusal, not only for the many important and carefully recorded facts it contains, and the valuable suggestions it affords, but also as a good example of the manner in which such an investigation as that so ably concluded by Dr. Buchanan, should be carried out. In this particular instance the inquiry has failed to actually prove that the cream was the source of infection, whilst there has been no investigation as to the manner in which the suspected cream may have become infected. But the results of this inquiry have been so far satisfactory that suspicion has been aroused, and the attention of the profession directed towards a possible source by which scarlatina may be propagated.

◆

REGISTRATION OF BIRTHS, DEATHS, &c.

The Irish Medical Association has lately devoted much time and consideration to the very unsatisfactory condition of the Act in force at present regulating the registering of births, deaths, and marriages in Ireland, confided to the dispensary medical officers, and came to the conclusion that repeal of the statute in force was necessary, not only for the public benefit, but for the interests of the registrars, they accordingly set themselves to work on the matter and consider what suggestions could be made which would—whilst benefiting the public interests as well as those of the registrars, at the same time—have precedents and be acceptable to Parliament, which was found to be no easy task. The Committee of the Council of the Association after mature consideration thought the best course to adopt was to follow up as nearly as circumstances admitted the English Registration laws, whereby they were enabled to show precedents, and although their project is not perfect, nor does it contain all which they could wish to obtain, yet it will probably meet with universal approval, for it is one which, whilst guarding the public interests and materially improving the position of the registrars, will be likely to find favour with the legislature. We understand that the Right Honourable the Earl of Donoughmore has been entrusted by the Association with the introduction of the Bill proposed by their Council, and that the preliminary submission to the various authorities interested in the matter has met with approbation. The Bill to amend the registration of births and deaths in Ireland suggested and drawn up by the Irish Medical Association has so far met with approval, and has been introduced to Parliament and printed by order of the House of Commons; in due course the Bill will come before Parliament during next session, when we hope it will be passed. So far as the public are concerned, the new Bill if passed will be a great boon, inasmuch as it will remove many of the disabilities and difficulties at present suffered. So far as the registrars' interests are concerned, we are glad to observe that the Bill provides extra remuneration and less trouble. The new Bill provides that the registrars shall receive 2s. 6d. each for the first 20 registries each quarter, amounting to an addition of £6 a-year to the present emoluments of each registrar. The remaining clauses enact important amendments in detail as to the machinery of registration calculated to facilitate the public and the medical officers in the performance of the function, and to make more effectual the record of births and deaths. We shall, in our next issue, lay before our readers the most important clauses of the Bill and any explanatory notes which they may seem to require. If this Bill should become law in next session of Parliament, as we have every reason to hope that it may, the Irish Medical Association will have done enough valuable public and professional work in this alone to justify its existence and to deserve the confidence of Irish medical men.

◆

Notes on Current Topics.

A New Luxury.

A MARSEILLES correspondent of the *Chemist and Druggist* states that arrangements are being made for supplying London with a substance known as "Marseilles butter." It is produced at a large stearine candle manufactory at Marseilles, where 500 hands are employed and where several tons weight of this substance are turned out weekly, it being known under the name of "Margarine, Graisse alimentaire and Beurre factice." The correspondent says:—"It is most artistically prepared, equalling in appearance the finest Epping or Dorset qualities, and it keeps well. But it will not go down at Marseilles, and a suitable market is now being sought for this spurious alimentary substance." Possibly the "Graisse alimentaire" is as palatable and nutritious as the best churn produce, but we hope it will not find its way to our tables under any false designation, or under the protection of Mr. Sclater-Booth and the English shopkeepers' trades unions.

Signs of Arsenical Poisoning in the Heart.

MR. ROBERT HARVEY, in the Indiana *Medical Gazette*, notices a fact which has not previously been made so fully known as he puts it, viz., the condition of the endocardial membrane after poisoning by arsenic. The author has collected together the facts relating to a very large number of arsenical poisonings, and on the subject now specially named he reports as follows:—

"The condition of the lining membrane of the heart is given thirty-three times, and is a point which should be carefully noted in future. In eight cases only in which it was carefully examined was it found to be natural. In two cases by Dr. Warburton the endocardium was deeply stained, but the action of running water rapidly removed the congested appearance, which does not seem to have amounted to ecchymosis.

"In twenty-three cases it was found congested or ecchymosed, the appearance being apparently confined to the left ventricle in most of them. The mitral valve was stained with bluish spots of extravasated blood in a case reported by Dr. Harris, of Shahjahanpur, in February, 1870. This officer reports seven cases of arsenical poisoning in three years, in five of which this endocardial congestion was present."

Horse Flesh and Tapeworm.

M. DECROIX, of Lyons, attributes the greater frequency of tænia mediocanellata at the present day, as compared with instances of tænia solium, to the growing practice of the employment of raw meat as a therapeutic aid, and the fashion of eating under-cooked meats. The habitat of the tænia mediocanellata, in its larval or cysticercous stage, is, as is well known, in the flesh of oxen and sheep; and M. Decroix points out the impossibility, in many cases, of ascertaining its presence in this stage. He urges the advisability of horse flesh being prescribed where it is deemed necessary to give meat in the raw state. He states that not only is the flesh of the horse more nutritious than beef, mutton, or pork, but that it has the further advantage of not being infested with any parasite having man for its host.

The Properties of Gallium.

THE recently discovered metal gallium melts at 81·1° Fahr., so that it liquefies when held in the hand. When solid, the metal is hard and resistant, even to a few degrees below the melting point. It can be cut and possesses a slight malleability. When fused, it adheres easily to glass, on which it forms a beautiful mirror, whiter than that produced by mercury. It oxidises but very superficially when heated to redness in the air, and does not become volatile. The density at 59° Fahr. is 4·7, that of water at 39·2° Fahr. being 1. Excepting mercury, which only becomes solid at 37·9° Fahr., there is no other element which liquefies at so low a temperature as gallium.

A Cholera Pestilence.

ONE of the most terrible outbreaks of cholera on record occurred this summer, in the village of Golwood, in Bombay. The population was more than two hundred, of whom more than half died in three days. The disease appeared at noon on June 4th, and before daybreak next morning there had been fifty-seven deaths. On the 8th all the survivors fled. The disease displayed extreme virulence, some cases proving fatal in twenty minutes. In these cases the ordinary cholera symptoms were absent, and the body at the first stroke of the disease became livid, convulsed and shrunken. Gross neglect of sanitary measures is the apparent cause, as it is stated that the people were living in inconceivable filth. Cholera appears to be unusually prevalent this year, outbreaks being reported from various parts of India.

An Unhealthy Locality.

IN a report which has been recently issued by the medical officer of health for Poplar we have a description of a particularly unhealthy part of that district. The area in question contains about 22 streets, courts, alleys, and places, with 208 houses. These houses were found, when specially inspected for the purpose, to contain 267 families, and an aggregate population of 1,115 persons. The official representation contains a description of the various courts, alleys, and streets of this area, which appears most completely to justify its condemnation as unhealthy. The large proportion of the houses ar declared to be "unfit for habitation." Forty-three deaths occurred within this area during the year 1875, which is equivalent to a death-rate of 38·6 per 1,000 of the enumerated population of the houses, 1,115 persons; whereas the death-rate in the whole of Poplar is 24 per 1,000 for the natural year 1875.

Attention has been drawn to this feature of the report by most of the daily papers, as though the above disclosure is something quite extraordinary and exceptional. We are afraid, however, that many such districts are to be met with not only in London, but in many other large towns. It is nevertheless a good representation of one of those nests of disease, poverty, and crime, which unfortunately can still be found without much trouble, and which some future hygienist will look back upon as an insanitary curiosity of the 19th century.

Vaccination in Keighley.

The vaccination officers of the Keighley Union have just made their annual report to the guardians. We have not yet received this report, but we see from a notice of it in a contemporary that the agitation which has been taking place in that locality, and to which we have frequently drawn the attention of our readers, has been already attended with the unfortunate results which we anticipated. During the year 1875, 1,019 births are reported to have occurred within the union, and at the end of the year 549 of the children, or 53·8 per cent. were unvaccinated or otherwise unaccounted for. In Keighley itself the proportion unvaccinated was so high as 60·4 per cent. These figures contrast in a striking manner with those recently published for Leeds, where the percentage of children unvaccinated or unaccounted for during 1875 was only 1·9. Moreover, the above facts strikingly justify the remarks which we recently made in one of our editorial articles, and in which we showed that if this opposition goes on much longer, some alteration will have to be made in the Vaccination Acts, even at the risk of making them more stringent. It has been justly observed that the material for another fatal epidemic of small-pox in Keighley is being accumulated at an alarmingly rapid rate; and not till then, perhaps, will the eyes of the public be open to the mischief which has been caused by the fanaticism of the opponents of vaccination.

The Mechanical Action of Violet Light.

The *Scientific American* says that M. Paul Bert's recent investigations as to the cause of the change of colour in the chameleon have led him to a discovery of considerable importance, since it indicates a mechanical effect of light, and more especially of the violet rays, hitherto entirely unknown. He traces the changes of hue of the reptile to minute corpuscles or chromoblasts, which are located either below the dermis or at the surface of the skin, according as they are affected by certain nerves which are respectively analogous to the vaso-constrictors and vaso-dilators. When the chameleon is placed half in red light and half in violet light, obtained by passing sunlight through coloured glass, the portion on which the red light falls remains of the normal yellow colour, while that affected by the violet light changes to a greenish-black hue. This same effect can be produced by suitable nerve excitations and divisions, showing that the accession of colour on the skin is absolutely caused by the rising of the coloured corpuscles to the surface; while, when the latter remain inert, the natural yellow hue of the creature continues unchanged. Hence it would appear that the coloured corpuscles, like certain chemical substances, are not equally affected by all the rays of the spectrum, and that in the violet-blue rays alone resides the property of mechanically moving the chromoblasts and drawing them to the surface.

How Railway Accidents Happen.

The gross disregard of life and limb exhibited by railway directors was never more culpably exemplified than in the case of the Flying Dutchman. From the report just submitted to the Board of Trade, we learn that on the 24th May last, when the accident happened, the train was going at the rate of sixty miles an hour down an incline of 1 in 400, and round a curve of 45 chains radius, when the engine left the rails, just where it was "lifted" only five days previously, the ballast having been thrown out for the purpose, just depriving the sleepers of a considerable amount of support. It will in no way surprise the public to learn that an accident happened to the Flying Dutchman under the circumstances; the wonder is rather that it should have so often run its wild course without before coming to grief, and sacrificing the lives of every one who might have been unfortunate enough to be boxed up in the carriages. The condition of the permanent way, as described by Captain Tyler, is simply abominable, for the officials whose duty it was to keep the permanent way in order must have known that the "strap-bolts" and "through-bolts" were too far apart, and therefore could not resist the strain of an engine weighing forty-nine tons, and dashing over them with a speed of sixty miles an hour. Under the circumstances it was no wonder to the Government Inspector that the bolts gave way and were bent under such strains, that the rails became bulged under the engine in the middle of their lengths, and that the carriages were thrown off them. It was, indeed, most fortunate that the engine itself remained on the line, and that in spite of the destruction caused to the transoms after the carriage left the rails, most of the passengers escaped without serious injury. We cannot but read of such a hair-breadth escape without a shudder. Nothing can excuse the reckless conduct of the directors of a large railway company for having exposed travellers to such fearful risks, and which in this instance was chiefly brought about by a silly desire to outstrip a competing line in a race against time.

The Spontaneous Combustion of Coal.

In the report just issued by the Royal Commissioners appointed to make inquiry into the causes of the spontaneous combustion of coal in ships, and of which a long and able review has been given in the columns of the *Standard*, there are many interesting and important facts to which Professor Abel and Dr. Percy have drawn the attention of the government. It appears that pyrites appear to be the only sulphur combinations occurring in coal, which, by their oxidation, promoted by the presence of moisture and by mechanical conditions favourable to the accumulation of the heat developed by such oxidation, are liable to give rise to what is called the spontaneous ignition of coal. Carbon, in a finely divided condition, has the property of absorbing and condensing within its pores large volumes of certain gases, among which is oxygen. The condensation of gas by a porous body is attended by the development of heat, proportionate to the extent of that condensation. A good illustration of this action is furnished by the very porous charcoal prepared for the manufacture of gunpowder. This has to be protected against rapid access of air for some time after it has been removed from the carbonising retorts, otherwise the charcoal, though it may have been allowed to cool down perfectly, will become heated upon exposure to air, to such an extent as to ignite spontaneously. Ignition is not uncommon during the grinding of the charcoal, owing to the extent of surface thus brought into contact with the air. The spontaneous ignition of oiled cotton or silk waste is due to the same law. The porous fabric serves as a vehicle for exposing the readily oxidisable oil or grease, in a finely divided condition, to the air, and thus favouring a rapid oxidation. These facts have a direct bearing on the spontaneous ignition of coal. The finer the particles of the latter; the greater is the facility for absorbing oxygen and thereby developing heat. After a careful investigation of this part of the subject, Professor Abel and Dr. Percy say it does not appear practicable to apply ventilation with any prospect of guarding against the accumulation of heat in some portion of a cargo of coal. The renewed supply of oxygen furnished by the introduction of a fresh volume of air would obviously favour the process of absorption, "so that a period would be reached sooner or later when the development of heat would be most seriously promoted by ventilation, some time before ignition demanded the total exclusion of fresh air." The conclusion is therefore warranted, both on scientific grounds, and from the evidence of facts, "that it is inadvisable to attempt through ventilation of cargoes in coal-laden ships." It is only to be regretted that through the lack of sound scientific advice the Board of Trade should have exercised its influence in the wrong direction, so as to aggravate the evil it sought to cure.

Hospital Saturday Fund.

THERE appears to be a fair prospect that the Saturday, or Workmen's Fund, will this year be more successful than the two previous years of its existence. On Saturday last the annual collections were made in the streets for the metropolitan hospitals. About 160 ladies had volunteered to take charge of collecting boxes at the corners of the principal London thoroughfares. In the evening the boxes were carried to the offices of the Fund, where they were opened and handed to seventeen clerks of the National Bank, who had given their services gratuitously, for the purpose of having their contents counted and duly noted. Shortly after nine o'clock Captain Mercier and several members of the Council of the Fund, met Mr. Jabez Hogg and other governors of Charing-cross Hospital, in the Board-room of that hospital. Captain Mercier stated that up to that time the street collecting boxes that had been opened had yielded upwards of £100 in excess of the entire street collection to the Fund of last year. Up to a quarter to nine the street boxes had yielded £577 About £450 had also been received during the day from other sources, and when he referred to the fact that they would be receiving money from *employés* of large firms, and from various combinations, for the next three weeks, it was impossible to say what would be the actual amount realised for the Saturday Hospital Fund, but he hoped it would double that of last year. Votes of thanks to the ladies, and to the Charing-cross Hospital authorities for the use of the Board-room, were unanimously carried, and a general expectation shared that the collection for 1876 would reach a very handsome figure.

Orthopædic Hospital in Dublin.

IN addition to the accommodation afforded by the National Orthopædic Hospital of Ireland, the starting of which in Dublin we noted the week before last, and of which Mr. Ormsby, of the Meath Hospital, is the working surgeon, the surgery of deformities is to receive a special provision for it by a second institution—the Dublin Orthopædic Hospital which has been opened in Ushers Island in the same city. The surgeons of the institution are Mr. Swan and Dr. Bookey of Stevens's Hospital, and the consulting staff are Mr. Hamilton and Mr. MacDonnell, of the same hospital. Whether either or both or neither of the new hospitals prove to be a success, the sick poor will gain an advantage, and we are not sorry to see an attempt to specialise a class of cases which are somewhat unsatisfactory of treatment within the wards of a general hospital, no matter how carefully the surgeon may do his duty. It will be for the surgeons of the new Orthopædic Hospital to justify their establishment by showing that they can attract patients and produce satisfactory results. There seems, at least, to be a concurrence of opinion that the public is in want of orthopædic specialists in Ireland.

The Death from Violence in a Lunatic Asylum.

THIS unfortunate case has at last come to a termination. In passing sentence upon the defendant, *John Smith*, the attendant at Camberwell House Asylum, Mr. Lushington, remarked that he had carefully weighed the whole of the evidence, and could come to no other conclusion than that the ribs of the patient Wimberley were fractured through violence. It had been stated that the ribs of the patient were very brittle, which would show that it required but little violence to break them. With regard to the evidence of the two epileptic patients, he had read what they stated before the coroner, and could find little difference in the statement made before this court by them. He should certainly take them as competent witnesses, and they stated that defendant kicked the patient in the ribs more than once. He wished to say that, with regard to asylums, no doubt many things might go on which it would be impossible for the doctors and managers to see, although, as in this case, they have done everything possible. He, however, felt bound to say he believed the two witnesses, and could come to no other conclusion but that the defendant grossly ill treated the patient of whom he had charge. Every keeper who had charge of patients was bound to remember that he should keep his temper, and that no provocation should tempt him to commit acts of violence upon such patients. He should not, he felt, be doing his duty as a magistrate if he passed over such a case lightly. He, therefore, ordered the defendant to pay the full penalty under the Act, viz., £20, or, in default of distress, three months' imprisonment.—The money not being paid, the defendant was removed in the prison van.

With respect to this sentence no one will think that the punishment inflicted upon the prisoner is more than he deserves, and certainly it is to the interest of the medical staff and managers of lunatic asylums that the case has so terminated. While in this instance the doctors of the asylum have been exonerated from any ill-treatment or bad management on their part, the blame has been thrown upon the right party; and the case of John Smith will in future be a warning to keepers, and show them that in undertaking the personal charge of the insane they incur too great a responsibility to indulge in any cruel or vindictive treatment of their patients.

The Profit upon Sanitation.

The Medical Officer of Health for Southwark, Dr. Bateson, has availed himself of the opportunity he possesses to compare within the last year the mortality of his district within and without the Peabody Buildings. These buildings are a model of structural perfection, cleanliness, and order, and are inhabited as a rule by a temperate and provident class of artizans, and it was to be expected that their health would contrast favourably with that of the squalid, dirty, and intemperate with whom the locality abounds. This anticipation has been abundantly verified by Dr. Bateson's figures, for he finds that the death-rate of the large population within the Peabody Buildings is only 12 per 1,000, while that of the outside parish is 24·5, a gain of 100 per cent. in favour of cleanliness and ventilation.

Surgeons for Servia.

The English contingent to the Turkish army is growing speedily larger, six surgeons from London and one from Dublin having left last week. The Government of the Porte are ready to accept all duly qualified and competent volunteers, to whom they pay on enrolment £25, to enable them to reach their head-quarters, and salaries of £12, £16, or £20 per month while on service, according to the rank in which they are placed. An opportunity of seeing plenty of field surgery is thus afforded to any enterprising young men who are not afraid to smell powder, and are ready to rough it a little in pursuit of a knowledge of their profession.

Galway College.

The *Belfast News-Letter* says, a short time ago a Commission of Inquiry visited the Queen's Colleges. The object of the inquiry was to determine whether it might not be possible to amalgamate some of the now existing Chairs, without impairing the efficiency of the several colleges. It was thought by some that if this were possible, the salaries of the present staff of professors could be increased without involving a demand for an additional grant from parliament. Some uneasiness was felt by those interested in the fate of the Queen's Colleges, lest that the commission, under an allegation of economical intentions, should in any way contribute to the difficulties which the Colleges have already encountered. The commission has not yet, so far as we are aware, presented its report; but we understand that it has been pronounced generally against the suggested amalgamation. This rumour obtains credence from the fact that the Government intends to fill up the vacancy in Galway College, caused by the death of Professor Lupton. We are, therefore, at present disposed to think that there is no ground for the fears which were freely expressed; and we think that the Government cannot have had any hostile intention as regards the Queen's University. Whatever lowers the position of Galway College endangers the other colleges. It is the threatened portion of the line, and cannot be too carefully guarded. The avowed determination of its opponents is to reduce it to an intermediate school. The friends of education must stand by the Galway professors, who have ever been the staunchest supporters of the Queen's University.

Arts Education as a Qualification for the M.D. in the Queen's Colleges.

The Irish Government have resolved to unite the professorship of Latin in Galway with the professorship of law in Belfast, in consequence of the small number of students in Latin in Galway. The additions to the salaries of the professors in the Queen's colleges will probably amount in all to £4,000.

Poisoning by Chloral Hydrate.

An inquest was lately held at Silloth, upon the body of the Rev. John Harvey, D.D., formerly minister to a large congregation in Edinburgh. In March, failing health compelled him to resign, and he has since been seeking rest in England. On arriving at Silloth he complained of being exhausted. At half-past nine he went to bed. He could not sleep, and at midnight got up and took a narcotic, consisting of 60 grains of bromide of potassium, and what he considered would be a teaspoonful of hydrate of chloral, though he did not measure it. About five o'clock next morning his wife became alarmed by his breathing, and found he was unconscious. Medical aid was sought, and Dr. Leitch, the local medical practitioner, was soon in attendance. He found the patient in an almost comatose state, and took measures to try and rouse him, and succeeded so far that he induced him to walk about the room. His physical powers, however, soon failed him, and, on lying down, he again became unconscious, in which state he remained until his death at eight o'clock. Dr. Leitch was of opinion that death had resulted from a dose of hydrate of chloral, not in excess of what the deceased had been in the habit of taking, but so large that his weakened physical condition had been unable to resist its action.

Fraudulent Liebig's Extract.

We last week reported a prosecution by the excise officers of the vendor of Liebig's Liquid Extract of Meat for selling, without a wine licence, an article containing a considerable quantity of spirit. The report did not sufficiently distinguish between the Liquid Extract of Meat and the ordinary Liebig's Extract sold in a semi-solid form, and largely used as a nutritive by the profession. The composition of the Liquid Extract was exposed by a prosecution of the vendors last October twelvemonth, which will be found in full detail in this journal. It was then sworn by the analyst to be nothing but "a concoction of Tarragona wine, sweetened with sugar, flavoured with pimento and allspice, and containing only a very small portion of extract of beef, but about 15 per cent. of pure alcohol." The seller of the preparation was prosecuted under the Food and Drugs' Act, for selling an article which was different from what it was described to be by the vendor, who represented that it was composed chiefly of pure extract of beef, together with wine and a small quantity of fine old brandy and quinine. The analyst, on the contrary, declared that the preparation contained only a trace of extract of beef, no quinine, and no brandy. We recall attention to the matter lest the repute of the genuine Liebig's Extract might suffer from its being confounded with this fraudulent concoction, which is sold in bottles of somewhat the shape and size of porter bottles.

The firm who make and sell this precious mixture are, we are glad to observe, bankrupt, so that the chemists who retail it have no remedy against them for any damage which they may suffer in consequence of having sold it in ignorance of its constituents. In the recent prosecution two chemists were fined £12 10s. each for selling it.

By latest telegrams a violent outbreak of yellow fever is reported at Savanah.

The Howard Medal of the Statistical Society of London will be awarded in November, 1877, to the author of the best essay "On the Condition and Management—past and present—of the Workhouses and similar Pauper Institutions in England and Wales, and their effect on health, intelligence, and morals of the inmates." The President has given the sum of £20 to be presented with the Howard Medal in November, 1877.

The following is the subject for the Jacksonian Prize of the Royal College of Surgeons for the present year, viz.—"The Treatment of Cancer of the Rectum, particularly as regards the possibility of curing or relieving the patient by excision of the affected part." The essays must be delivered on or before December 30. The subject of this prize for the ensuing year is "The Disease of the Lymphatic System known as Hodgkin's Disease or Lymphadenom." For the Triennial Prize, which consists of the John Hunter Medal executed in gold to the value of fifty guineas, or, at the option of the successful author of the dissertation, of the said medal executed in bronze, with an honorarium of £50, the prize will be awarded to the author of the best essay "On the Radicles of the Lymphatic System in relation to the External and Internal Surfaces of the Body."

Correspondence.

"THE SALARY OF THE BLACKBURN MEDICAL OFFICER OF HEALTH."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I read your remarks concerning the present remuneration of the above medical officer in your issue of the 9th ult. with much interest. I am not surprised at your observations thereon, as you are evidently unacquainted with the cause of such a state of affairs. I admit without any hesitation that the salary is in this case a mere nonentity when compared with those of similar appointments in this country. There is a question of *medical ethics* at the root of this evil. It is the fault of the medical officer, and not of the Board under which he serves. When the aforesaid gentleman was selected for the office, ability and acquirements were not considered as items in his favour. He who would work cheapest was the man whom the Board, or rather, its members required, and in this competition Mr. Martland, the present medical officer of health, was successful by a long way, but whether it was creditable to him is another question. The other candidate asked a respectable salary for disagreeable work, but Mr. Martland, to the surprise of his opponents, submitted that he would undertake the duties for the wonderful amount of £25. He did so, no doubt, with the intention of ultimately obtaining an increase by application, an application which has since been made, and, of course, scouted. When I take into consideration the manner whereby he came into office, I cannot see one reason why his salary should be increased. Any kind of medical officers can be obtained for any kind of salaries, but if a good man is wanted he must be remunerated accordingly. I do not wish to convey that Mr. Martland is not equal to the calling, far be it from me to do so, but any person can see that a town with nearly 100,000 inhabitants cannot be looked properly after by a medical officer for the above-mentioned salary. The salary, in my opinion, should be somewhere about £400, and then it would only be on an equality with similar appointments in this country. It would, of course, be unwise, as well as unjust to the ratepayers of this borough to increase the salary of the present officer to that amount. Let there be a proper election by the committee who preside over the office, and let the appointment be conferred upon him whom they consider the best man. In this way an accomplished health officer will be secured for the benefit of the people. It is a great drawback that some members of our profession will work absolutely for anything which they are offered. I cannot conceive why such should be the case, but such is the case, and may well be considered degradation to the profession.

It is high time to be on the alert now, when small-pox is spreading from almost the centre of the town. The most neglected places may escape for a while every form of epidemic disease, but that direful scourge, small-pox, will probably teach the people, ere it disappears from here, the necessity of proper sanitary arrangements. In conclusion, I would advise members of the profession not to accept such appointments by contract, as tradesmen do. Let them not even become candidates where such rules are observed as have hitherto been done here. Let them consider the advice of Pollonius to his son Laertes, in the play of "Hamlet":—

> "To thine own self be true,
> And it shall follow as the night the day,
> Thou canst not then be false to any man."

Apologising for trespassing so much on your valuable space,

I am, Sir, your obedient servant,

Blackburn, 14th August, 1876. Johannus.

COMPULSORY SUPERANNUATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I have read with some surprise and regret your remarks on the letter of "J. D. R. K." in your last impression. Your desponding tone on the prospects of superannuation is different to that which you generally utter on subjects which have equity on the face of them. Why should the Poor-law medical officer be the only man expected to die in harness. I cannot see the force of your conclusions as to what you seem to think an abuse of the principle in the case of those gentlemen who, after receiving superannuation allowance, have had vigour enough remaining to embark in another branch of practice. This is not the view adopted in the matter of retiring pensions in the army and navy. I know a retired navy surgeon who after serving some fifteen years retired on a pension of 200*l.* a year in the vigour of manhood, allowing him to perform the duty of medical officer of a very large and laborious district under the medical charities, and I am sure he is only one of hundreds who have been similarly rewarded for past services. I have passed some 30 years in a very extensive dispensary district before and after the passing of the Medical Charities' Act, a district in which I am obliged to drive over bad roads and walk over worse, too bad to ride or drive on. I am now verging fast towards "the sere and yellow leaf," when the synonia of the acetabula and the entervertebral substance are—the former more scanty the latter less cartilaginous. But I suppose until I make my appearance on crutches I shall be held capable of performing my duty, and therefore not entitled to a retiring pension. Why should a principle be adopted with us which is not thought equitable towards a police constable? I pause for a reply.

SENEX.

[Our correspondent entirely misconceives our meaning if he supposes that we in anyway sympathise with the objections the existence of which we noted on the part of guardians and ratepayers. We were called upon to initiate an agitation, and we are of opinion that it would be alike imprudent and vain to do so. We confess, however, that while we recognise and would urge the claim of a Poor-law medical officer to superannuation as of right whenever he should become actually incapable, from any cause, of efficiently discharging his duty, we would not consider it reasonable to ask that, like the army medical officer, he should receive a retiring pension after a certain term of service, while still fully competent to discharge his duty. If such argument were laid before the Government it would be at once replied, as was said on former occasions, that the Poor-law medical officer does not devote "his whole time" to his official duties and has other resources, while the army officer is solely and wholly the servant of the Crown, and therefore bound to be provided for by the State.—ED. *M. P. & C.*]

AUDI ALTERAM PARTEM!—MR. JONATHAN HUTCHINSON'S ESSAY ON TOPICS OF MEDICAL AND SOCIAL INTEREST. (EARLY MARRIAGE AND FEMALE MEDICAL EDUCATION.)

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have, in common with the rest of the profession, learnt so much from Mr. Jonathan Hutchinson in all departments of medical science that I always feel, when I differ in opinion from that most distinguished man, that in all probability I may be in the wrong. Still, as every rational being is obliged to decide according to the best evidence before him, I cannot help writing to explain how it is that I am not at all convinced by many of the arguments adduced by that gentleman in a recent address of his to the British Medical Association in London in opposition to female medical education, and one or two other social questions.

First of all, I am quite of Mr. Hutchinson's opinion when he says that it seems clear to him that the great danger to which English civilisation is exposed comes from the quarter of late marriages. I will quote his own words: "It appeared to me that the medical profession, cognisant as it is to so large an extent with secrets of individual and family life, owes it as a duty to society to take every means of making known its conclusions; and that we could come to no other conclusion than that the preservation of sound physical, mental, and moral health in both sexes is connected in an essential and inevitable manner with the facilities offered for early marriage." (*a*)

This is a thesis I have always adhered to; but I shrewdly suspect that Mr. Hutchinson does not see all the difficulties which lie in the way of carrying out the idea he so benevolently aims at. And yet the long and important contributions which have of late years been made to most of our lay journals on the question of the *Darwinian Law* might have long ago permeated medical literature and been applied to solve this knotty point in hygiene. It remains now surely fully ascertained that our race, in common with all other races, has the power of increasing its numbers with giant strides (doubling, for instance, in some twenty or thirty years), if food and other requisites of human life be but abundantly enough bestowed upon us. If, then, early marriages were to come into fashion suddenly, there cannot be any doubt in the minds of those who have studied political economy in the works of the masters of that science, such as Malthus, Ricardo, Say, or the two Mills, that in the present unprepared state of the public mind concerning the duties of parents towards the numbers and quality of their offspring, the effect would be that other myriads of unfortunate human beings would be introduced into a world where they would find no room for them, and either struggle and die an early death, or remain in that celibate condition their parents had shunned *for the sake of their health*, as Mr. Hutchinson would seem to advise.

Sismondi, John Mill, and Joseph Garnier have shown that, wherever dangerous prejudices are not ingrained in the minds of the inhabitants of a country, it is the custom of the people to think most anxiously and seriously about the number of their family. M. Maurice Block says, for instance, that the French peasantry and artizans, when married, are careful only to bring into the world two or three children; and Sismondi tells the same of the peasantry of the Val d'Arno. Consequently, although I warmly adopt Mr. Hutchinson's advice as to early marriage being necessary to save society from vice and sorrows of all kinds, I must add the proviso that was given as advice to the citizens of Amiens some years ago by M. Charles Dunoyer, the mayor of that town, that young married persons must let prudence regulate their unions, and above all, see that these unions are not more prolific than their industry.

With respect to the elaborate argument made use of by Mr. Hutchinson to prove that women ought not to study medicine or take diplomas in medicine, I would reply to most of these by observations which are usually thought applicable to other questions in social science. There are, it is clear, *some* women who desire to gain knowledge of medicine. Why prevent these women? And if they are incapable of learning much about that science, let the maxim "caveat emptor" hold here as in other departments of trade. No one need employ a woman as a medical adviser unless he or she likes. As to diplomas, they are, I presume, merely certificates, to mark that a particular person has acquired knowledge or proficiency in any art; and if a woman know much about anatomy, physiology, medicine and surgery, I don't see why the Faculty of Medicine of Paris or of Zurich, &c., does wrong by certifying to the fact.

But I take the liberty to go further. I believe that the study of medicine by educated women is one of the best and most hopeful of modern movements, and for this reason: All thoughtful persons have lately confessed that civilisation progresses just in so far as knowledge and science abound. If so, how is it compatible with any idea of a truly civilised state of society that not only a vast proportion of the male sex should be, as at present, in the profoundest ignorance of all that relates to physiology, but that the *whole* of the other sex should be debarred from studying sciences which are so intimately connected with morality and social well-being as are the sciences taught to practitioners of medicine? How can we expect to get rid of the evils of society so long as so much want of knowledge exists?

To say that the practice of medicine is *indelicate* is, to my mind, a total absurdity. To a mind well educated in what is right and wrong, indelicacy is not associated with any part of an organism; and I maintain that if it be wrong for a good woman to study and practise medicine, it must be equally so for a good man to do so. In my opinion, the idea of indelicacy being one of the necessary features in the question of female doctors, is only the *twaddle of the nursery*.

(*a*) *Brit. Med. Jour.*, August 19, 1876.

There is one argument for women studying medicine that has always had great weight with myself, because, as I have above indicated, I am embued with the idea that society requires, in order to be happy, earlier marriages, but very much smaller families. I have long been convinced that the equalisation of population with food and the means of subsistence, will never be seriously comtemplated until women, as well as men, begin to look their destiny in the face, because the ignorance and so-called *delicacy* of women, as at present educated, make them an easy prey to poverty and all kinds of evils, which greater knowledge of physiology would enable them to escape. With regard to the other topics alluded to by Mr. Hutchinson, such as the C. D. Acts, the alcohol debate, and the One Portal System, I dare not venture to treat them at the fag end of a letter, but hope you will permit me to write to you about them at some future occasion.

I remain, Sir, your obedient servant,

Charles R. Drysdale, M.D.,
Physician to the North London Consumption Hospital,
Consulting Physician to the Farringdon General Dispensary, High Holborn.

17 Woburn Place, W.C., London,
August 21, 1876.

Literature.

ON THE FUNCTIONAL DISEASES OF THE URINARY AND REPRODUCTIVE ORGANS. (a)

This may be termed a "classical" work, there are so many references to authors more or less learned, and there are so many quotations, of a polyglot description, all through the book. In one page we have six authors, writing in five different tongues, laid under contribution. The first two chapters are urinary—45 pages—the remaining 250 pages are reproductive in more senses than one, and deeply impress the reader with the writer's extensive acquaintance with medical literature.

As may easily be imagined, spermatic matters occupy two-thirds of the book. It seems sad that so many phthisical patients should have to confess to impure practices; but in a paper read to the Medical Chirurgical Society some years since, Dr. Smith asserts that 22 per cent. suffered from spermatorrhœa. Worse still is the discovery of an "ingenious writer that *clergyman's throat* is to be ascribed to spermatorrhœa?"

The treatment of this peculiar disease is to be attempted by the caustic catheter, the administration of chloral hydrate or bromide of camphor; *phosphorus*? The old remedy, perchloride of iron, in doses gradually increased to one and a-half or two drachms of the tincture is given thrice daily. Finally, fornication is used as a remedy. Lallemand, B. Phillips, Mr. Erichsen, the Greek Church Cicero, Dugald Stewart, and Strauss, all appear to be summoned, as authorities in recommending this more than questionable piece of advice.

The last chapter is devoted to the subject of sterility in the female, and is a very good *resume* of the various forms of disease leading to this condition. Lastly, the appendix contains parts of articles from the *Lancet*, and extracts from the reviews of the first edition, the general tendency in these articles being to lament that so little has been done in the way of throwing light on functional diseases of the male sexual system. Surely there is no want of works on the subject now, any deficiency having been made up by the comprehensive and exhaustive treatise under consideration.

A HANDBOOK OF THE THEORY AND PRACTICE OF MEDICINE. (a)

We are glad to welcome a second edition of this already well-known handbook. The first edition at once became acceptable to the profession, and established for this work a place in the front rank of handbooks. The second edition, so soon called for, will further raise its position. It is a much neater and handier volume than the first, which was too fat to be handled with comfort. The same care has been exercised in this as in the former edition, and each page is full of information. Though a handbook of 800 pages seems at first sight too large, it would be impossible to use any compression of the contents. Dr. Roberts has the faculty of putting a very great deal into a limited space, and further than that, he puts his matter very clearly, so that there is no obscurity about what he means. This work is not only a capital work for students preparing for their examinations, but it is well adapted for practitioners who wish to have the most recent information in a convenient form. For busy practitioners it seems the thing they require, and we fancy it will soon be found in some easily reached place in most surgeries, and be found well thumbed, too. Not only is the diagnosis of each disease carefully given, so that after the perusal of this work the busy man need fear no consultation, but the pathology is good; and further, the section devoted to treatment is excellent, and will be found instructive by most readers. If the work is faulty anywhere, it is in the little attention given to the light physiology throws on the treatment of disease. As, for instance, nothing is said about the restriction of the nitrogenised elements of food in the dietary of the subjects of Bright's disease of the cirrhotic type; and yet this matter is most important in giving relief from the different sequelæ of kidney incompetency, as well as being of no slight moment as regards the progress of the affection. The reduction of the amount of nitrogenised waste can only be achieved by limiting the nitrogen in the food; and such reduction of the amount of waste is the first step in the treatment of this malady. Similar fault might be found with the treatment of palpitation, where the different forms of palpitation, each requiring its own appropriate treatment, are not sufficiently carefully discriminated. Somewhat oddly, in a work generally so well done, insomnia is omitted from the list of cerebral symptoms, and yet it is a most important matter, diagnostically as well as therapeutically. Cerebral anæmia, too, though it possesses a distinct set of symptoms, and is also an important and frequent malady, seems, so far as our search goes, to be conspicuous by its absence. Dr. Roberts has succeeded in turning out a first-rate book, but there is just sufficient lacking to call for his attention in the preparation of the third edition, which will, in all probability, soon be called for. Dr. Roberts must keep the needs of the practitioner as clearly in view as he does the necessities of students, and then his handbook will take a position from which it can never be dislodged in our time.

NOTES FROM OUR EXCHANGES.

A Case of Complete Artesia Vagina.

Dr. A. F. Shelly, of Philadelphia (*Med. and Surg. Reporter*, April 29, 1876), publishes the notes of a case of the above affection which came under his notice, the only one of its kind met with in an experience of twenty-four years' practice. The patient was 15 years of age, well-developed, and for a year previous to the detection of the imperforate condition of the hymen had complained at monthly intervals of pain in her stomach. Was first seen by Dr. Shelly March 13th, 1874, suffering from excruciating pain, principally from an inability to pass water. On attempting to draw off the water, he discovered "a large tumour pressing upon the perineum, and separating the labia majora, like the size of a child's head in the last or expulsive stage of labour." Percussing the lower part of the abdomen he found "dulness extending in an arc from the middle of Poupart's ligament on one side to the same point on the other side, and arching up four inches above the symphysis pubis." Further examination fully revealed the true condition of the patient. In consultation with Dr. Ellerslie, Professor of Obstetrics in the Jefferson Medical College it was decided to evacuate the fluid by means of a puncture made with a grooved needle. Dr. Shelly lays great stress upon the manner in which this apparently simple operation is performed, as he believes therein lies the true secret of success.

(a) "On the Functional Diseases of the Urinary and Reproductive Organs." By D. Campbell Black, M. D., formerly Phys. to the Royal Infirmary, Glasgow. Second Edition. London: J. & A. Churchill. 1875.

(a) "A Handbook of the Theory and Practice of Medicine." By Fred. T. Roberts, M.D., B.Sc., &c.; Assistant-Physician to University College Hospital, &c. H. K. Lewis, Gower Street. Second Edition. 1876. Pp. 803.

Holding the needle between the thumb and index finger with the groove upwards, he introduces it from below upwards, in an oblique manner, so as to form a perfect valve for the purpose of excluding every particle of air.

He suggests for the purpose an ordinary grooved needle, rounded at the point, well grooved, with very sharp edges.

After the puncture was made "a very dark, pitchy fluid was discharged, in a sluggish manner, to the enormous quantity of at least four pints in the next twenty-four hours; after that the discharge appeared to be of a mixed bloody mucous and muco-purulent character, and continued to be so for the period of about three weeks, becoming, however, less and more watery, and at last very trifling in quantity."

Subsequent treatment consisted of rest in bed and perfect quietness until the next menstrual period, April 7th, twenty-eight days from the time of first seeing her. The menses came on quite naturally, and flowed through the puncture, through which the point of a bistoury was inserted, "*without cutting however.*" She was then allowed to get up and go about, taking gentle exercise, and permitted a more liberal dietary. The second monthly period commenced in the first week in May, when a circular portion of the hymen was excised sufficient to admit of introducing the index finger. The excised portion was at least the sixth of an inch in thickness. Subsequent dilatation was practised to insure success. The patient afterwards menstruated regularly, and enjoyed perfect health.

The dangers attendant upon atresia vagina are pyæmia, peritonitis, and endometritis.

Medical News.

Army Medical Service.—The following gentlemen competed successfully for appointments in Her Majesty's Army Medical Service, at the examination held at the University of London on August 14th, 1876:—

	Marks.
Allin, W. B.	2220
Ryan, M. R.	2081
Robbins, H. J.	1976
Reynolds, E. O.	1935
Carey, J. T.	1925
Morris, J. J.	1869
Rainsford, W. J. R.	1858
Tuthill, P. B.	1850
Williamson, J. F.	1840
Boyd, J.	1790
Hayes, A. E.	1782
Hewett, A.	1745
Johnston, P. H.	1744
Boulger, J.	1675
Laffan, G.	1675
Roche, E. A.	1625
Emerson, J. B.	1615
Robinson, R.	1600
Allen, W. H.	1505
Lamprey, J. J.	1485
Murchison, F.	1435
Bourke, U. J.	1409
Keith, A. C.	1395
Peyton, J. S.	1340
Russell, G. M.	1325
Large, W. B.	1305
Carleton, A. W.	1295
Brodie, J.	1285
Gunning, R. C.	1255
Cotton, H.	1230
Hunt, J. P.	1215
Hughes, G. A.	1180
Eager, F. G. L.	1055

Naval Medical Service.—The following is the list of candidates for the Naval Medical Service who have passed the recent competitive examination held at the University of London:—

	Marks.
Walsh, H. W. D.	2025
Henwood, J. D.	1970
Mugliston, T. C.	1935
Williams, T. E. H. T.	1915
Guppy, H. B.	1875
Armstrong, G. W. F.	1857
Connell, J. J.	1822
Williamson, F.	1685
Rae, W. M.	1675
Kellett, L. H.	1599
Newland, C. F.	1540
Dow, J. C.	1535
Wade, A. B.	1485
Barcroft, P. J.	1480
Murdoch, R.	1460
Corcoran, L. W.	1420
Twigg, G. D.	1335
Browning, J. N.	1315
Fogerty, G. J.	1310
Bookey, W. J. B.	1240

◆

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Reading Cases.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the Medical Press and Circular, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat, after it has passed through the post.

Subscribers who have not yet sent in their subscriptions for last year are respectfully reminded of the omission.

The Balham Mystery.—As M.D. makes an assertion without giving any reasons for the views he has formed we cannot insert the letter in its present form.

Dr. Ormsby's paper shall appear if possible in our next.

To the Editor of the Medical Press and Circular.

Dear Sir,—Would you kindly suggest the remedies most likely to correct an ammoniaco-phosphoric diathesis?

A patient of mine, æt. 60, is subject frequently to large urinary deposits, from which he has intervals of freedom, urine abominably fœtid when these deposits are present and then decomposes with great rapidity. We cannot trace these changes to dietetic causes. Health apparently good; habits active and salubrious. Ordinary tonics, mineral acids, &c., seem to have no corrective effect. A specimen of deposit enclosed, which, when present, is alarmingly profuse.

Yours very truly,
Discipulus.

[The administration of salicylic acid in 8 or 10 grain doses thrice daily combined with 5 grains of biborate of soda and given in an ounce of water with some syrup or glycerine will be found of material benefit. If there is prostatic enlargement and consequent retention of urine the water should be removed by the catheter. The use of salicylic acid internally has been found very serviceable in some urinary cases lately treated.—Ed. M. P. & C.]

Dr. Edgar Flinn's "Case of Triplets with a Fourth Blighted Fœtus" shall appear in our next.

W. R. V.—The malady is one requiring no *special* knowledge to treat; consult a legally-qualified practitioner in your own town, there is no necessity for you to go to London. Members of the profession are not given to spread news of the so-called "secret diseases" of their patients; it is the quack who does this in order to terrorise his victims with a threat of exposure for the purpose of extorting money. Satisfy yourself that the gentleman you consult is duly qualified, and the result cannot but be satisfactory to yourself.

Nutbrown.—Freckles are a term used rather loosely for different kinds of discolouration of the skin. The genuine freckle is a definite yellowish mark of small size, most evident on very fair skins, and on parts exposed to light, especially the forehead, face, and neck. They will disappear occasionally, and are always worse in summer weather and after solar exposure. The ordinary applications advised are bitter almond emulsion, weak solutions of corrosive sublimate, sour buttermilk, or oatmeal and water, and have succeeded in rendering them less unsightly by repeated applications of solution of sulphurous acid. This is especially useful on the backs of the hands, but its disagreeable smell renders it less useful for the face. The stains of chloasma of brown and yellow colour, common on covered parts, as the chest, loins, and abdomen, yield to sulphurous acid or a solution of hyposulphite of soda mixed with vinegar and freshly applied, after using soap and water freely to moisten the surface of the skin. So far as I know cutaneous discolourations are little influenced by internal treatment, but the intimate connection between supra-renal disease and the remarkable condition termed bronze skin should not be forgotten. "Kittoe's" lotion is composed of muriate of ammonia, ʒj; aq. fort, a pint; lavender-water, q.s. To be applied with a sponge thrice daily.—Ed. M. P. & C.

If Dr. Balmforth will forward the communication referred to, we will endeavour to find space for it in our next, provided it is not too long.

DUTIES OF CONSULTING SANITARY OFFICERS.

To the Editor of the Medical Press and Circular.

Sir,—Will you oblige me by replying in your next issue to the following question—viz.:—Can the Board of Guardians of a union, as sani tary authority, in the event of a dispute arising *in any part of their district* between the other sanitary officers, the people and themselves, compel the CONSULTING SANITARY OFFICER to (in addition to his attending the meetings of their Board for consultation, &c., &c.) VISIT *any part of their district* and make a report on the case in dispute.

I am, Sir, yours truly,
JUSTICEA.

[The 10th Clause of the Public Health Act provides that "every sanitary authority shall appoint such sanitary officers, including a medical superintendent officer of health (who corresponds to consulting sanitary officer) when deemed necessary as the L.G.B. shall in each case direct . . . and the said Board shall assign to . . . the medical superintendent officer of health . . . his respective functions and duties in the discovery or inspection, or removal of nuisances, in the supply of pure water, in the making or repairing of sewers and drains, and in generally superintending the execution of the sanitary laws within the district."

In accordance with this enactment, the L.G.B. fixed the duties of the consulting sanitary officer as follows:—

The duty of the consulting sanitary officer shall be to attend meetings of the guardians acting as sanitary authority, whenever required to do so, and to advise them on all matters and proceedings requiring medical knowledge and advice in the administration of the sanitary laws.

In our opinion the visiting and examination of a nuisance is an essential part of the advising of the Board, and is, therefore, within the duty of the consulting sanitary officer.—ED. M. P. & C.]

◆

VACANCIES.

Leeds Infirmary. House Surgeon. Salary £100, with board. Address Dr. Heaton, the Infirmary.

Metropolitan Free Hospital. Assistant Physician. Honorary. Applications to the Secretary.

Newcastle-on-Tyne Infirmary. Junior House Surgeon. Salary £50, with board. Apply to the Secretary.

Wolverhampton General Hospital. Assistant House Surgeon. Board, but no salary provided. Address the Chairman of the Medical Committee.

Toxteth Park, Liverpool. Assistant Medical Officer to the Workhouse and Infirmary. Salary £100, with board and apartments. Address the Secretary.

◆

APPOINTMENTS.

BROWN, J. J., M.B., F.R.C.P.Ed., Senior Assistant Medical Officer to the Royal Lunatic Asylum, Morningside, Edinburgh.

CORR, Dr. W., Medical Superintendent of the Barony Parish Hospital, Glasgow.

FORTY, D. H., L.R.C.P.L., M.R.C.S.E., Resident Medical Officer to the Swansea Hospital.

JESSETT, F. B., F.R.C.S.E., Medical Officer of Health for the Erith Urban Sanitary District.

LEACROFT, J. W., M.B., Medical Officer for the Inkberow District of the Alcester Union, Warwickshire.

MCNAUGHTON, J., M.B., L.R.C.S.Ed., Medical Officer to the General Prison for Scotland, Perth.

NOLAN, C. J., L.K.Q.C.P.I. & L.M., L.R.C.S.I., Medical Attendant to the Royal Irish Constabulary, Shanagolden and Foynes.

O'CONNOR, M. R., M.D., Medical Officer, &c., for the Carrigaholt Dispensary District of the Kilrush Union, co. Clare.

PRICHARD, A. W., M.R.C.S.E., Assistant Surgeon to the Bristol Royal Infirmary.

ROBERTS, A., M.R.C.S.E., Medical Officer of Health for the Keighley Urban Sanitary District.

◆

Marriages.

ELLIOT—NOYES.—On the 31st ult., at S. huke's Church, Torquay, Henry Francis Elliot, L.R.C.P.Ed., of Ruyton, Salop, to Amy, fourth surviving daughter of the late Henry Criue Noyes, of Thruxton, Hants.

ILOTT—RING.—On the 31st ult., at the Parish Church, Streatham, Herbert James Ilott, M.B., M.R.C.S., of Bromley, Kent, to Theresa Georgiana, third surviving daughter of the late Charles Riug, of Upper Tooting and Doctors' Commons.

PALMER—AMY.—On the 23rd ult., at the Parish Church, South Hackney, T. Hurlstone Palmer, M.R.C.S.E., youngest son of John Palmer, of Baginton, Coventry, to Marian, youngest daughter of the late F. H. Amy,

WOODBURN—HELLEN.—On the 23rd ult., at the Parish Church, Ulverston, William Harrison Woodburn, Surgeon, Broughton-in-Furness, to Mary Ann, only daughter of Joseph Hellen, of Park View, Ulverston.

◆

Deaths.

BOGIE.—On August 21, at Fruids Park, Annan, Agnew Black Bogie, M.D., aged 57.

CROSBY.—On August 21, at Bootham, York, Thos. Crosby, M.R.C.S.E., aged 66.

CURRAN.—On August 26, at Youghal, co. Cork, Jas. Curran, L.R.C.S.I., aged 50.

EDEN.—On August 24, at Norwood, Thos. Edward Eden, M.R.C.S.E., aged 85.

HANSON.—On September 1, at Crescent Villa, Brentford, Newton Hanson, M.D., M.R.C.S.L., aged 76.

LAWRENCE.—On August 21, at Queen Square, Bath, Joseph Lawrence, M.R.C.S.E., aged 51.

ROBERTON.—On August 24, at Holly Bank, New Mills, John Roberton, L.R.C.S.Ed., aged 79.

WILKINSON.—On August 20, at Limerick, Dr. Thomas Wilkinson, Surgeon-Major Royal Limerick Fusiliers.

GENERAL NURSING INSTITUTE for TRAINED HOSPITAL NURSES.

5 Henrietta Street, Covent Garden, W.C.
A. EBSWORTH, F.R.C.S., Director.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.—The WINTER SESSION will commence on MONDAY, 2nd OCTOBER, with an Introductory Address by DR. BLANDFORD, at 4 p.m., in the Hospital.

The system of Clinical Teaching has been arranged so as to afford every student personal instruction in the wards from the Physicians and Surgeons themselves.

The courses of Lectures on Physiology and Surgery have been remodelled in conformity with the new regulations of the College of Surgeons.

Special departments have been organised for practical instruction in Midwifery, Ophthalmic Practice, Skin Diseases, and Dentistry. Lectures on Public Health are given by the Lecturer on Medicine.

Pathology, Morbid Anatomy, Psychological Medicine, and Comparative Anatomy are taught in distinct courses.

Instruction is given in all the special modes of medical and surgical investigation.

The following paid offices are offered for composition annually—viz., Obstetric Assistant, Curator of the Museum, Demonstrator of Anatomy, Medical and Surgical Registrars.

The House-Physicians and House-Surgeons are selected by merit from among the Perpetual Pupils without payment, board and lodging in the Hospital being provided at the expense of the Governors.

The Wm. Brown Exhibition of £100 per annum, tenable for two years, and £40 per annum, tenable for three years; the Brackenbury Prizes of £35 each annually, are awarded, along with various other prizes, by competition among the students.

The prospectus may be obtained by application to the Secretary at the Hospital, and any further information will be given by Dr. Barclay, Treasurer, or Dr. Wadham, Dean of the Medical School, either personally or by letter.

THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.

PATRON:—H.R.H THE PRINCE OF WALES.

This Institution was founded in 1869, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develop the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £40 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote.

Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c. can be had at the office,

40 MOLESWORTH STREET, DUBLIN,
W. O'NEILL, Secretary

NATIONAL ORTHOPÆDIC HOSPITAL OF IRELAND.

For the Treatment of Club-Foot, Contractions, and Distortions of the Limbs, Spinal, and all other bodily deformities.

7 UPPER KEVIN STREET, DUBLIN.

President—The Right Hon. the Viscount POWERSCOURT, K.P.

Vice-President—The Right Hon. Lord ANNALY.

Committee—Right Hon. G. B Owens, M.D., J.P., Lord Mayor of Dublin; Charles Leslie, Esq., J.P., 25 Merrion Square, N.; Major Dopping Hepenstal, D.L., Derrycassan, co. Longford; S. S. Archer, Esq., 22 Great Charles Street; R. W. Boyle, Esq., J.P., Milltown House, co. Dublin; Major Hartley, Beech Park, Clonsilla; James Tyrrell, Esq., 2 Merrion Square, East; A. E. Graydon, Esq., Newcastle House, Rathcoole, co. Dublin.

Consulting-Surgeons—George H. Porter, M.D., M.Ch. (*Honoris Causa*), Univ. Dub.; F.R.C.S.I., Surgeon in Ordinary to Her Majesty the Queen in Ireland, and Senior Surgeon to the Meath Hospital and County Dublin Infirmary, &c. Philip C. Smyly, M.D., Univ. Dub.; F.R.C.S.I., Surgeon in Ordinary to His Grace the Duke of Abercorn; Surgeon to the Meath Hospital and County Dublin Infirmary, &c.

Surgeon—Lambert H. Ormsby, M.B. Univ. Dub.; F.R.C.S., Surgeon to the Meath Hospital and County Dublin Infirmary, &c.

Bankers—Boyle, Low, Murray, and Co., 35 College Green, Dublin.

Collector and Secretary—Mr. W. Brereton, 97 Upper Leeson St., Dublin.

There is now established in Dublin,* for the first time, an Institution entirely devoted to the treatment of these maladies. As medical statistics prove that Irish children suffer more than any others from that variety of distortion which is generally known as "Rickets," there is special scope in this city for its beneficial agency.

The relief afforded will be entirely gratuitous, the poverty of the sufferers being the only recommendation required.

Subscriptions and Donations will be received by Boyle, Low, Murray and Co., Bankers, 35 College Green, for credit of the National Orthopædic Hospital of Ireland; by Lambert H. Ormsby, Esq., 12 Lower Fitzwilliam Street, Dublin; by The Consulting Surgeon; by any Member of the Committee; or by the Collector and Secretary, Mr. William Brereton, 97 Upper Leeson Street, Dublin.

N.B.—Subscribers of £1 1s. are presented with Tickets for recommendation.

Medical Men and Clergymen, *of all denominations*, are at liberty to recommend patients.

*The Dispensary is open daily, at 10 a.m., for Patients suffering from all kinds of Bodily Deformity, at 7 Upper Kevin Street, Dublin.

SCHOLARSHIPS in SCIENCE. — ST. BARTHOLOMEW'S HOSPITAL and COLLEGE.

—A Scholarship of £100 open to Students who have not entered at any Metropolitan Medical School, will be offered for competition on September 27. Subjects:—Chemistry, Botany, Zoology, Physics. An Exhibition of £50 in the same Subjects, and One of £40 in the Subjects of Preliminary Education, open to Students who have entered at the Hospital in October, will be competed for in October. For particulars, apply personally, or by letter, to the Warden of the College, St. Bartholomew's Hospital, Smithfield, E.C.

UNIVERSITY COLLEGE, BRISTOL.

MEDICAL SCHOOL.

The WINTER SESSION will commence on MONDAY, October 2. Prospectuses may be obtained on application to

GEORGE F. BURDER, M.D., Hon. Sec.

Medical School, Old Park, Bristol,
August, 1876.

CHARING CROSS HOSPITAL MEDICAL SCHOOL.

SESSION 1876-77.

The SESSION will commence on MONDAY, OCTOBER 2nd, when the Introductory Address will be delivered by J. MITCHELL BRUCE, M.D., M.A.

The Hospital contains 160 beds. This number will be considerably augmented before the termination of the present Session, probably making a total of 200 beds. This, together with the 36 beds of the adjoining Royal Westminster Ophthalmic Hospital, to the practice of which Matriculated Students are admitted, will make a total of 236 beds available for clinical teaching.

SCHOLARSHIPS, MEDALS, AND PRIZES.

Two Entrance Scholarships of the value of £30 and £20 respectively are awarded annually in October, for which candidates are required to give notice of their intention to compete on or before Saturday, September 16th, 1875.

The Golding Scholarship of £15 is awarded annually to Students who have completed their first year

The Llewellyn Scholarship of £25 is awarded to Students who have completed their second year.

The Governor's Gold Medal for Clinical Medicine and Surgery is awarded to Senior Students. The Pereira Prize of £5 is open to all Matriculated Students, and is awarded for the best Clinical Reports.

Silver and Bronze Medals and Certificates of Honour are awarded in the various classes.

APPOINTMENTS OPEN TO STUDENTS.

Medical Registrar (salary £40 per annum).
Surgical Registrar (salary £40 per annum).

Resident Medical Officer.
Resident Surgical Officer
Resident Obstetrical Officer.
Assistant Medical Officer.
Assistant Surgical Officer.
Clinical Clerkships.
Surgeons' Dresserships.
Pathological Assistant.

Open to all Matriculated Students without additional fee.

The Fees for the entire Course of Lectures required by the Examining Board amount to £80 7s., including a fee of £2 2s. for Matriculation (which involves no examination), and they may be paid in five separate instalments of nearly equal amount. The first is payable on entrance, the second on 1st of February following, and so on, the fifth instalment being due at the commencement of the third year.

The composition fee for Dental Surgery, including Matriculation, is £42 2s.

A Prospectus, containing much additional information, will be forwarded on application to the Dean. FRANCIS HIRD, Dean.

THE LONDON HOSPITAL MEDICAL COLLEGE.

The next WINTER SESSION will commence on MONDAY, OCTOBER 2nd, 1876, when the Introductory Lecture will be given by Dr. ANDREW CLARK, Senior Physician to the Hospital.

The perpetual fee to Lectures and Hospital Practice, with two years' Practical Anatomy, is 90 guineas if paid in one sum, or 100 guineas if paid by three instalments. Special entries can be made to Lectures or Practice.

The Hospital contains about 800 beds. The In-patients during 1875 were 5,804, and the Out-patients, 40,717.

1, 2. Two Entrance Science Scholarships, value £60 and £40;
3, 4. and two Buxton Scholarships, value £30 and £20, will be offered for competition at the end of September. Entries for the above must be made on or before the 20th September.
5. A Scholarship, value £20, in Human Anatomy, for first-year's Students.
6. A Scholarship, value £25, in Anatomy, Physiology, and Chemistry, for first and second year's Students.
7. A Hospital Scholarship, value £20, for Clinical Medicine.
8. A Hospital Scholarship, value £20, for Clinical Surgery.
9. A Hospital Scholarship, value £20, for Clinical Obstetrics.

A Prize of £5 to the Student who has attended most Midwifery Cases during the preceding twelve months. The Duckworth Nelson Prize, value £10, for Practical Medicine and Surgery (Biennial). Money Prizes to the value of £60 given annually by the House Committee, for zeal in Dressing Out-patients and knowledge of Minor Surgery.

For particulars as to Appointments see the Prospectus, which will be forwarded on application to the Secretary, Turner Street, Mile End, E.

Greatly increased facilities are now afforded by adjacent railways and tramways for rapid transit from the neighbourhood of the Hospital to other parts of London. The East London Railway Company's station is directly opposite the Hospital. Lodgings can be obtained in healthy localities in the immediate vicinity of the Hospital, at a very reasonable charge.

OWEN'S COLLEGE (MANCHESTER ROYAL) SCHOOL OF MEDICINE.

The WINTER SESSION will commence on the 2nd OCTOBER. The Registration of *Former* Students will take place on the 25th and 26th September, and of *New* Students on the 4th to the 14th October.

Prospectuses will be forwarded on application.

J. HOLME NICHOLSON, Registrar.

ST. THOMAS'S HOSPITAL, ALBERT EMBANKMENT, WESTMINSTER BRIDGE, S.E.

—The MEDICAL SESSION for 1876 and 1877, will commence on MONDAY, the 2nd OCTOBER, 1876, on which occasion an Address will be delivered by Mr. FRANCIS MASON, at Four o'clock.

Gentlemen are informed that the Admission Fees to Practice and to all the Lectures may be paid in one of two ways:—

1st. One Hundred Guineas, paid on entrance, entitle a Student to unlimited attendance.
2nd. Payment by three instalments, namely, of £40, at the beginning of the first year, £40 at the beginning of the second year, and £30 at the beginning of the third year, entitles a Student after payment of the third instalment to unlimited attendance.

Special Entries may be made to any Course of Lectures or to the Hospital Practice; and a modified Scale of Fees is arranged for Students entering in their Second, Third, or any subsequent year.

Private Classes for Students preparing for Matriculation, and for the Preliminary Scientific Examination, and M.B. Examinations, of the University of London, or for other Examinations, are conducted by members of the Staff, and embrace instruction in Chemistry, Natural Philosophy, Botany, and Comparative Anatomy, Physiology, Anatomy, and Materia Medica. Gentlemen can attend these Classes without becoming Students of the Hospital.

PRIZES AND APPOINTMENTS FOR THE SESSION.

First Year's Prizes. Winter.—Entrance Scholarships of £60 and £40 awarded after an Examination in Physics, Chemistry, Botany, and Zoology. The Wm. Tite Scholarship of £30. College Prizes—£20 and £10. Summer Prizes—£15, £10, and £5.

Second Year's Prizes. Winter.—The College Scholarship of 40 guineas, tenable for two years. College Prizes—£20 and £10. Summer Prizes—£15, £10, and £5. The Assistant Dresserships, Clinical and Obstetric Clerkships are open to Students who have passed the Primary Examinations at the Royal College of Surgeons.

Third Year's Prizes. Winter.—£20, £15, and £10. In-Patient Clinical Clerkships and Dresserships.

The Cheselden Medal is awarded after a Special Examination in Surgical Anatomy and Surgery. The Mead Medal, awarded after a Special Examination in Practical Medicine and Hygiene. The Solly Medal, with a Prize of at least 10 Guineas, for a collection of Surgical Reports. The Treasurer's Gold Medal, for General Proficiency during the entire course of Study. The Grainger Testimonial Prize, for Physiological Essay illustrated by preparations. The Two House Physicianships. The Two House Surgeoncies. The Resident Accoucheurships.

A Medical and a Surgical Registrarship, at a honorarium of £40 each, is awarded to Third or Fourth Year's Students.

MEDICAL OFFICERS.

Honorary Consulting Physicians—Dr. Barker and Dr. J. Risdon Bennett.
Honorary Consulting Surgeon—Mr. Frederick Le Gros Clark.
Physicians—Dr. Peacock, Dr. Bristowe, Dr. Murchison, Dr. Stone.
Obstetric Physician—Dr. Gervis.
Surgeons—Mr. Simon, Mr. Sydney Jones, Mr. Croft, Mr. MacCormac
Ophthalmic Surgeon—Mr. Liebreich.
Assistant Physicians—Dr. Ord, Dr. J. Harley, Dr. Payne.
Assistant Obstetric Physician—Dr. Cory.
Assistant Surgeons—Mr. F. Mason, Mr. W. W. Wagstaffe, Mr. A. O MacKellar.
Dental Surgeon—Mr. J. W. Elliott.
Assistant Dental Surgeon—Mr. W. G. Ranger.
Resident Assistant Physician—Dr. Sharkey.
Resident Assistant Surgeon—Mr. Clutton.
Apothecary—Mr. S. Plowman.

LECTURERS.

Medicine—Dr. Bristowe and Dr. Murchison.
Surgery—Mr. Sydney Jones and Mr. MacCormac.
General Pathology—Dr. Payne.
Physiology and Practical Physiology—Dr. Ord and Dr. John Harley.
Demonstration in Physiology—Dr. T. Cranstoun Charles.
Descriptive Anatomy—Mr. Francis Mason and Mr. W. W. Wagstaffe
Anatomical Demonstrations in the Dissecting Room—The Anatomical Lecturers, Dr. R. W. Reid and Assistants.
Special Anatomical and Microscopical Demonstrations—Mr. Rainey.
Practical and Manipulative Surgery—Mr. Croft and Mr. MacKellar.
Chemistry and Practical Chemistry—Dr. A. J. Bernays.
Midwifery—Dr. Gervis.
Physics and Natural Philosophy—Dr. Stone.
Materia Medica—Dr. Payne.
Forensic Medicine—Dr. Stone.
Comparative Anatomy—Mr. C. Stewart
Ophthalmic Surgery—Mr. Liebreich.
Botany—Mr. A. W. Bennett.
Dental Surgery—Mr. J. W. Elliott and Mr. W. G. Ranger.
Demonstrations of Morbid Anatomy—Dr. Greenfield.
Lectures on Morbid Anatomy and Practical Pathology—Dr. Greenfield.
Mental Diseases—Dr. Wm. Rhys Williams.
State Medicine—Dr. Alfred Carpenter.

W. M. ORD, M.B., Dean.
R. G. WHITFIELD, Medical Secretary.

Any further information required will be afforded by Mr. WHITFIELD.

ON THE TREATMENT OF INFANTILE CONGENITAL CLUB-FOOT.

By W. J. Little, M. D.

(*Continued from page* 171.)

Another practical point, the neglect of which is apt to entail future trouble is, that gentle, painless, passive exercises and manipulations should be employed *pari passu* with the instrumental treatment, whether or not any operation has preceded it. (*a*) Long detention in any apparatus in one fixed position, whether it be that of extension or flexion of the foot, causes painful rigidity of structures which are naturally destined to constant daily movements. It is a fact that long retention of a part in one fixed position is a cause of pain when the part is again moved. This is observed by sound persons during many of the avocations in life. In like manner, the child whose foot has been too long held in any retentive apparatus, experiences pain when the part loses its support, or when the surgeon attempts to manipulate it. The young child instinctively offers resistance to the handling, the older child energetically opposes by means of volition the surgeon's efforts to move the parts. By frequent proper removal of the splint, by winning the confidence of the child through gentle patient usage, the entire treatment of infantile congenital club-foot can be painlessly conducted. Violent manipulation of these cases under anæsthetics is a barbarism. (*b*) We frequently meet with varus cases in which the foot has been adducted and flexed to a right angle, and has been so long retained in that position that difficulty is experienced in extending it and abducting it. It is true, that undue adduction with heel and sole contraction are characteristics of varus, but it should at the same time be remembered that a moderate degree of congenital varus exhibits a natural position, such as the foot in health is required to assume amongst its numerous actions. I have had cases that, from undue retention in instruments, have never recovered the power of proper depression of the foot, such as is required in standing tip-toe. In some of these cases this condition has been brought about by repeated sections of the tendo-Achillis. By this means also an artificial talipes calcaneus is often produced. Allied to the necessity of the foot being exercised and manipulated in all natural deviations during infancy, is the necessity for the choice of a good apparatus for those cases which have not been thoroughly cured during infancy. There is no doubt that the ordinary ratchet-screw instruments so largely used in the present day, miscalled Scarpa's instruments, by their fixed condition allowing, when applied, no "play" in the ankle-joint, are, in that respect, much inferior to the real Scarpa shoe, to Stromeyer's modification of it, and to the further modification of it, which is known as my shoe.

Another practical rule, of the necessity of which I am convinced from long experience, is, that the surgeon who treats a case of varus, with or without operation, should, *until the natural range of motion at the ankle and toes* is fully obtained, apply the splints or other apparatus with his own hands, and renew them at least once a-day him-

---

(*a*) I again quote here, as I did in "Treatise on Deformities," [illegible], a few words from Mellet, "Manuel Pratique d'Orthöpædie," [illegible], "Manipulations are the life and soul of orthopædy, and few distortions are curable without them."

(*b*) Even after the surgeon has obtained full range of motion, an accidental interruption of treatment or neglect may, in a few weeks, cause considerable relapse. If the child have attained the age of eight or twelve months, the surgeon or parent has to deal with the temper of the child, and its wilful resistance to his efforts. Opposition from these sources can only be overcome by tact – the utmost gentleness combined with firmness, and a steady resolve not to be led into a perceptible struggle with the child. The causing of pain must be sedulously avoided, for the reason, that with patience and perseverance the cure can be effected without it.

self, or only allow it to be done by a well-qualified representative. Most splints or apparatus of the kind need, as a rule, removal once a-day. By no other course can the surgeon keep the thread of the treatment in his own mind and hands, and rarely without it does the case do justice to his wishes. I would lay down as a rule, that no case can be handed over to parental or domestic management, until the joint is fully and freely moveable to the full natural extent in all proper directions. Too many surgeons heedlessly sever the Achillis-tendon, and leave the ultimate and most important part of the after-treatment to an incompetent assistant, to the parent, or to an instrument-maker; practically, the case "takes its chance."

Much has been said about bringing the heel down to a right angle. I would say that nothing is permanently gained until the ankle can be *freely bent*, *extended*, *adducted*, and *everted* to the natural extent. There can be no doubt that the éclat which at first attended "division of the tendo-Achillis," and the benefit which promptly follows this operation in many cases in young children, has often been the cause of imperfect cure. The improvement visible immediately, or shortly after this operation, has led the surgeon and parent to be satisfied with the improvement already gained. The patient has been dismissed to the parent and instrument-maker before the bending and eversion of the foot was complete, and before the patient was enabled to tread as well upon the inner margin as upon the outer margin of the foot.

A powerful cause of delayed restoration or non-success of instrumental or operative treatment of congenital club-foot, springs from the innate difficulties attending it. Hence, in those deformities, the surgeon ought to leave nothing to incompetent persons. In the greater number of cases in which a surgeon performs any other operation than that for a congenital club-foot, he may calculate upon receiving larger assistance from nature. After an ordinary surgical operation, the wound will heal, the original natural parts left intact after the operation will perform their offices, even parts which have been injured will exhibit a tendency to the normal state of things. But in congenital club-foot, unless on the way towards cure, there is often exhibited a tendency to relapse into the original distorted state of things. So strong in many cases is this tendency, that it has suggested the idea that it is not merely the disposition of an elastic, semi-elastic, contractile, or tougher structure, to return to the form and length which it has possessed during the three, four, or five latest months of uterine life, when the distortion may have originated, and during the period that has elapsed since birth, but that there exists a tendency to revert to that state of evil, *nisus formativus*, which was formerly generally believed to be the cause of these affections during the earliest phase of embryonic development. The resistance to cure is naturally greatest in the most severe cases, severity not being measurable from mere external shape of the member, but from the number of the muscles affected. The gastrocnemial layer only, or the deep posterior layer of muscles of the leg also, the anterior tibial muscles, the respective layers of the sole of the foot, including all the ligaments and fasciæ, may also be contracted. We recognise the highest grades by the deep clefts behind the heel and in the sole, and by the tissues being so tense and resistant to the hand as if they were all more or less adherent and fixed together, a supposition anatomy does not justify. In no form of remediable complaint is there greater need of intelligent watchfulness and attention.

Another cause of delayed recovery I take to be the fruit of an insufficient estimate being formed by the surgeon of the difficulties of the cure, and of the parent never having been informed of the probable length of time during which the treatment may require to be continued, or at least during which a diligent attitude of watchfulness against the first signs of relapse should be maintained. It is comparatively easy to rectify the form and movement within a period of two or three months, in the case of a young infant; but the patience of the surgeon or parent is liable to flag during the number of years these cases, if once greatly mismanaged or neglected, cannot safely be left to themselves. When asked by parents how long the treatment or the attention of the parent or doctor will be needed, I now reply, "Until puberty, or until the child is old enough to take care of itself." Many medical men are prone to conceal the truth from the parents. I can with satisfaction say in relation to club-foot, that since I have told parents that their attention to prevent relapse will be required until adolescence or until the patient have quite grown up, and have distinctly placed the responsibility as to the final result on the parents' shoulders, I have rarely witnessed a relapse in one of my own private cases. It is an obligation upon the surgeon not to hand over the cured case to the sole management of the parents until he has thoroughly *instructed* them in the duties they will have to perform in order to maintain the cure. If it be possible, the surgeon should not entirely lose sight of the case until the patient is thoroughly competent to perform all the active locomotive acts of civil life.

A great cause of retardation of restoration has been the expense of *elaborate* instruments, the rapidity of the infant's growth, and the damage done to them by the frequent wettings by the child's secretions. Renewal of such instruments and their repairs, especially when the child has been permitted to walk before the cure has been completed, place formidable obstacles in the way of early successful treatment, and accounts for many disappointments.

Owing to want of means, the poor—our profession's most numerous clients—are the greatest sufferers by the supposed need of expensive apparatus, Whether in general or special hospital practice, it is practically impossible to keep pace with the demands for elaborate instruments.

In most hospitals some provision can be made for one set of instruments, but no known funds are available to meet the demands of the poor when the protracted use of apparatus becomes necessary, as in half-cured cases, hence augmented difficulty of locomotion and suffering. It becomes, therefore, a greater satisfaction to be enabled with confidence to point out the means by which, in at least this particular deformity, the use of expensive apparatus can be with certainty avoided.

Another cause of incomplete cure may arise from the occurrence of and interruption from one or more of the epidemic infantile diseases to which the very young are liable, or to want of breast-milk, severe bowel complaints, convulsions, and so-called difficulties of dentition, which I would attribute to the risks incidental to transition from the mother's milk to independent feeding.

Lastly, when cases have not been thoroughly restored in form and natural movements before the time of beginning to walk, ingenious and expensive mechanical contrivances are prescribed, either to help completion of cure, or to assist and correct errors in the act of locomotion. Such contrivances, *vulgo* irons, are often worn for years during the day time, the limbs returning at night into a worse position unless checked by a suitable retentive shoe. Some years ago I classed and wrote of these cases as relapsed ones. With my present experience this term would be a mere euphemism. I consider all such cases to have never been truly cured, the result of either misfortune, inattention or neglect of suitable treatment before or after leaving the surgeon's hands. For such cases, in which many structures have become additionally rigid from age, from undue walking in improper positions of the foot, long retention in unsuitable apparatus, and neglect of manipulations, the sufferer is apt to pass from hospital to hospital, or from private surgeon to private surgeon, to the manipulations of the pretended bone-setter, or the pretended dislocation-reducer, with or without the aid of anæsthetics. Repetition of section of the poor Achillis-tendon is undergone, as in Phillips's hands even to the twenty-second time. (*a*)

Other tendons and fasciæ are sometimes treated in a

(*a*) "De la Tenotomie sous-cutanée." Le Docteur Ch. Phillips, Paris 1841, p. 54.

similar way, and wholesale sub-cutaneous section in the mass of all the plantar tissues included between the integuments and the under surface of the tarsal bones has been again advocated. (See *British Medical Journal*, March 13, 1875, p. 339). Experience shows that the contracted arch of the bones of the tarsus in a young adult case of congenital club-foot can, after division of the superficial band of fasciæ and tendon of long flexor of the great toe be gradually unfolded and elongated by mechanical appliances, by manipulations, and by suitable exercises. I therefore regard the division in mass of all the plantar tissues as an unnecessary operation, and as one presenting peculiar disadvantages and probable future annoyance. (*a*)

There has already been too much of the knife in these imperfectly cured cases. I have, with rare exceptions, resorted to a single repetition of tenotomy, and I trust now, even more than ten years ago, to mechanical means and exercise.

The able surgeon who has carried out wholesale division of plantar muscles, tendons, arteries, nerves, and ligaments, remembered, doubtless, Phillips's and Guerin's long since published experiments on men and animals, which were intended to show the fearlessness and safety with which the largest arteries, veins, and nerves may be sub-cutaneously divided. Operations upon human beings frequently present different results from those observed in animals. The human tissues are equally tolerant of deep and large sub-cutaneous sections with those of animals, as far as regards the risks of bleeding, suppuration, and mortification. An animal may recover promptly from a deep section of vessels and nerves in a limb, and walk apparently well after it has recovered from the immediate effects of the operation. But the animal is unable to express his after sensations to us. The human nerves and vessels unite, but the human being can communicate his feelings, and inform us what unpleasantly imperfect union results even from sub-cutaneous sections. I have been consulted in two cases in which the peroneal nerve had been severed during the operation of dividing the outer ham-string, neither patient had recovered after many years from the total paralysis of the muscles on the outside of the leg and foot. I know another gentleman whose nervus communicans tibiæ was severed over thirty years ago, at the same time as the Achillis-tendon. He still complains of very unpleasant aberration of sensation along the outer edge of the foot.

I know a case also in which, twenty years ago, I divided the posterior tibial tendon, and doubtless the neighbouring artery, veins, and nerve. Many of the distal tissues were relaxed more effectually than was intended, and the arterial and venous trunks on the front of the foot are unpleasantly prominent and distended. These cases have confirmed me in the practice during tenotomy to keep as close to the tendon as possible, to employ no bold surgery, such as unnecessarily sweeping the knife, in the neighbourhood of any and especially of important parts.

As so much has been written about suppuration or delayed healing of the wound made in proposed sub-cutaneous tenotomy, it will not be out of place to mention here, that I have never witnessed the smallest particle of pus in the thousands of instances in which I have practised sub-cutaneous division of tendons. This result is attributable to the smallness of the puncture in the skin, and to the care taken immediately to cover the puncture with pledgets of lint and bandage. The number of considerable scars which I have seen in consultations respecting incompletely treated cases, shows that the operation has not been accomplished by a mere puncture afterwards nearly invisible. It is probable that suppuration has sometimes resulted from operators having fingered the wound after completing the operation.

A few words more with reference to the employment of elaborate instruments in congenital club-foot. Such are not necessary in cases which come under treatment before the child begins to walk. Valuable and necessary as they are in the treatment of cases which have been permitted to walk before a perfect restoration of form, movement, and function has been obtained, they are totally unnecessary before the age at which a child should walk. I may go much further, and say that infantile club-foot can be better cured without Scarpa's, or any other shoe, than with it. All elaborate instruments for infantile cases are simply articles *de luxe*. Indeed, they have not even that poor recommendation. From the circumstance that renewals and repairs often cause interruption of instrumental treatment and loss of time, they are mischievous, they act

---

(*b*) See also as to the operation of removal of the cuboid bone in *British Medical Journal*, May 13, 1876.

L. A. Sayre ("Lectures on Orthopædic Surgery," New York, 1876) has, in some cases of congenital club-foot, widely departed from safe principles of sub-cutaneous surgery. In an instance of double congenital varo-equinus, p. 120, headed, "Reduction of Dislocated Tarsal Bones by Force immediately after Sect. of Tendo-Achillis and Plantar Fascia," it is recorded that no disagreeable consequences resulted from the force employed. I would remark, in reference to this case, 1st, if it were, as stated, one of varo-equinus, that certainly no dislocation of tarsal bones exists in this form of distortion; 2nd, that the case could have been remedied without violence; and 3rd, that the photograph (fig. 67) taken after the supposed cure shows to the initiated that the main part of the most difficult part of the cure, viz., proper application of the inner margin of the right foot to the ground, and apparently that proper (full) bending of both ankles, had not been attained.

A case, page 123, shows the lengths to which impatience and violence may lead the surgeon, after it has been shown for nearly forty years by what means similar and far more severely deformed cases of varus have been fully restored. The case was that of an adult female, not one of congenital varus, which is confessedly the form which in adults offers the greater resistance to restoration, but a case of two years' duration only of (hysterical ?) spastic or paralytic equino-varus, which is not only a distortion less in amount than that which an adult congenital varus usually presents, but one in which, owing to its recent origin, the ligaments and fascia exhibit little resistance, and therefore the surgeon is enabled to remove the deformity with less than half the trouble required for the cure of adult congenital varus. The fig. 70 shows the comparatively small amount of distortion which existed. Under chloroform, Dr. Sayre "divided the tendo-Achillis and plantar fascia of the left foot, and was then *compelled* to divide the skin also, before he could restore it to position." From the word I have made italic and the context, I infer that the same force which is spoken of in other cases was used "to restore it to position" immediately after the operation, and doubtless the attempt was made to *secure* it in that position by means of apparatus. It is not to be wondered at that an ecchymosed, slough-threatening spot appeared on the fourth day at the base of the little toe, that by the twelfth day rigor, fever, delirium, and erysipelas set in. In about six months a very useful and nearly normal foot is said to have resulted. The fig. 21 does not justify in the eye of the initiated this opinion. The patient's life was indeed, as acknowledged, placed in great jeopardy by the operation. The use of violence, and, above all, the purposed division of the skin—a structure which is more easily extensible than all others of the body—evinced a total disregard of sound orthopædic and sub-cutaneous surgery.

By simple sub-cutaneous division of tendo-ach. and plantar fascia, by the omission of any attempt at once to straighten the part, and by *gradual* replacement of it in a suitable apparatus during the next three or four weeks, and without the use of any abrupt force, the case might with ease have been more fully restored in five or six weeks. In no orthopædic case is division of integuments justifiable. Sudden violence applied to joints is objectionable, even where no wound of any kind exists. The risk of mischief increases if violence be used, even when a pin-puncture-like tenotomy wound in the skin has been done, but to use purposed violence immediately after laying bare the plantar structures, by division of the skin itself, is courting destruction of the limb, or of the patient's life. The forcing a part into a rectified position in an apparatus, so as to produce a threatened slough at the base of the little toe, is only a degree less mischievous than *forcibly* pressing the tarsal bones into a proper position with the hand after tenotomy. (See Sayre, p. 115.) These remarks on Sayre's treatment would be out of place if he had intimated to his readers that he had no intention of recommending them to imitate his practice or of repeating it himself. Dr. Sayre's unfortunate departure from Stromeyer's treatment of club-foot, is redeemed in other parts of the article by the value he attaches to manipulations and instrumental treatment where no operation is requisite. Op. cit. p. 79. Sayre has repeated a mistake often made by others that "Dr. Little" had himself suffered from congenital club-foot. See on this subject Stromeyer's Beiträge already quoted.

often as a delusion to the attendants, who, regarding the *ignotum* as infallible, expect wonders from it, and are led to neglect other apparently more humble means. The tin splints and tin shoes, introduced by me many years ago, or the improved adjusting tin splint described by me in an article on orthopædic surgery in "Holmes' Surgery," second edition, have enabled me to accomplish better results in young infants than ever previously obtained by less simple means. These tin splints and side splints, with a roller bandage, constitute a sufficient armamentarium upon which the surgeon in remote country districts may safely rely, as far as mechanical means go, for the cure of his ptaient, if he will take as much pains, using his own hands, as if he were treating a bad fracture. A neglected fracture of a leg bone, and a consequent somewhat crooked leg, is a smaller evil as regards subsequent use of the limb, and the ability of the patient to perform the active duties of life, than a neglected imperfectly cured congenital clubfoot.

(*To be continued.*)

◆

PATHOLOGICAL ANATOMY OF THE BRAIN—LOCALISATION IN CEREBRAL DISEASE.

By Prof. Charcot.

Translated from *Le Progrès Medical.*

Chapter VI.

C. To return, gentlemen, to the paracentral lobule and ascending convolutions. These have already a history in experimental pathology, and I shall show you, by-and-by, that they also have a history in human pathology. I don't know whether the paracentral lobule has ever been the object of physiological investigations in the monkey—this lobule is present in the higher monkeys.

(a) Here an opportunity arises which I ought to seize for noting a fact, which is quite unique of its kind, but which lends a certain interest to this lobule in human pathology. This fact, which I proceed to lay before you, has been made out by a careful observer, M. Sander.

A child who died at the age of 15 had been seized in his third year with infantile spinal paralysis, which had caused more or less atrophy of all the limbs, especially of those of the left side.

The autopsy revealed in the spinal cord the lesions described by French authors. A minute examination of the brain showed that the two ascending convolutions on the outer surface were much shorter than is normal. They left a little of the island of Reil visible, and, besides, they were destitute of folds (*replis*). The paracentral lobule was quite rudimentary, and contrasted in this respect with all the other convolutions, which had been perfectly developed. The lesions were more marked in the right hemisphere than in the left, which might have been expected from the circumstance that the left side limbs had suffered most. The author is of opinion that in this case the limbs having been early and completely paralysed, in consequence of a serious spinal lesion, the motor centres, rendered inert at a period when they were in course of evolution, were in consequence arrested in their development. I allow that this interpretation appears to me worthy of being considered; yet it is to be regretted that the observer did not think of examining the nerve cells in the motor centres.

A case observed by M. Luys in a certain measure resembles the last. My colleague at the Salpetriere has noticed in a case of long-since-performed amputation atrophy of the cerebral convolutions on the side opposed to the amputated limb. Unfortunately, the exact seat of the atrophy was not defined, so far as I can recollect.

(b) This leads me to relate another fact to you, still referring to the department of the brain under consideration. The fact is this: the investigations of M. Betz go to prove that the pyramidal giant cells were only present in small numbers in very young children—not until later did they multiply, and then the increase took place to all appearances, under the influence of functional exercise. This observation deserves to be compared, on the one hand, with part of that of M. Lander, and on the other hand with an annotation of experiment, quite recently recorded by Mr. Soltmann. This writer—and I think that Professor Rouget (of Montpellier) has observed something of the same kind—had noticed that in newly-born puppies excitation of the regions answering to the seats of the motor centres did not produce any muscular movements in the corresponding limbs, but that some time after birth—about the ninth or eleventh day—these points became excitable. These observations, although few in number, deserve remark, as they seem to show that the motor centres are not pre-established (so to speak) anatomically so much as physiologically. They were developed with advancing age under the influence, no doubt, of functional exercise.

In support of this view, I will make a remark, with which I shall end the treatment of the special subject which has just had our attention. The large celled regions of the brain are of the "five-layered type," and their only anatomical peculiarity is the presence of these very giant cells. Now these last do not differ in any essential manner, morphologically, from pyramidal cells of a large kind, which possess, as appeared from Koschewnikoff's researches, protoplasmic prolongations, nervous processes belonging to motor cells.

It appears reasonable to ask whether these cells, and even those of the small kind representing the large ones in miniature, would not be likely, in certain conditions, under the influence (for example) of some abnormal functional excitation, to become developed, and (in a way) to give rise to supplementary motor centres, designed to replace the primitive centres, when these have been destroyed by some lesion or other. For example, one may thus understand how voluntary movements can be again produced in a member, in spite of the destruction of a motor centre; recovery from aphasia, which has been many times proved to have taken place in spite of the persistence of the lesion in the third frontal convolution, may furnish us with an instance of this.

D. To finish the exposition of the structure of the grey matter of the brain, I have only to add some very concise details of the peculiarities of that organism in the posterior parts of the encephalon. The regions where these peculiarities exist comprise, I repeat, the whole occipital lobe, the sphenoidal lobe, and the median and posterior parts of the hemisphere as far as the posterior edge of the quadrilateral lobe.

The general character of the grey matter in these regions is that the pyramidal nerve cells are less in size and number, as a rule, while the granulations, on the other hand, notably predominate. It is not that there are no large nerve cells there, but they are comparatively rare—"solitary," to use M. Meynert's expression. M. Betz adds that these cells have no distinct nervous prolongations, and that the protoplasmic processes even are little developed. The limits within which these features are observed in the brain correspond, according to many investigators, with the common *sensorium*. Were this interpretation exactly correct, it would follow that the cells just mentioned were the cells of sensation. This hypothesis is further grounded on other anatomical considerations, and on pathological data which, I shall notice again with additional details.

M. Moutard-Martin, Physician to the Beajon Hospital, Paris, has been nominated officer of the Legion of Honour, and MM. Perrin, Hugot, Wolff, and Masliurat-Lagimait, Chevaliers of the same order.

ON THE DUALITY OF THE SYPHILITIC CHANCRE. (a)

By Charles R. Drysdale, M.D., M.R.C.P. Lond.; F.R.C.S. Eng.

Senior Physician to the Metropolitan Free Hospital; Physician to the Bolsover Street Lock Hospital (Rescue Society), London; Consulting Physician to the Farringdon General Dispensary.

It is rather an unfortunate fact that medical science does not escape the lot of most parts of human knowledge, liability to confusion and obscurity. It was natural that such obscurity should linger longest in questions which were always discussed more or less *sotto voce*, such as those appertaining to venereal diseases. Hence it is only now that syphilis with all its curious collateral interests is becoming eagerly investigated by the ablest men in the profession; and there is every hope that this formerly *secret disease* may ere long become as well understood by the mass of the profession as typhoid fever, scarlet fever, or measles now are. I cannot say that I think that can at this moment be said of syphilis, and am about to give a very notable instance of the truth of what I now allege by the following quotations from two of the most esteemed syphilographers of Europe. One a distinguished English surgeon *primus suter pares*, the other one of the brightest ornaments of the Ecole de Médecine of Paris.

In the evening of February 1st, 1876, Mr. Jonathan Hutchinson delivered a brilliant address on syphilis at the Pathological Society of London, and among other phrases the following was printed in the *British Medical Journal*:—"Even in the more restricted sense, as implying that there are two distinct kinds of virus, to which are attributed two different forms of chancre, I think we may say of dualism that it is dead, and that the far simpler creed which attributes the soft chancre to contagion with inflammatory products produced by syphilis, but not, as a rule, containing its germs, is the one which now obtains general acceptance." A complete believer myself in the dualism of the chancre, I own that I was startled by an assertion so contrary to all I knew of authors writing contemporaneously on the question of syphilis: and happening to be in Paris a few weeks subsequent to the delivery of Mr. Hutchinson's paper, I took the opportunity to speak to Dr. Alfred Fournier (perhaps *the* greatest syphilographer of the day) as to his opinion of the dualism of the chancre. M. Fournier at once replied—"Cela ne se descente plus ici"—in the sense that no man in Paris at this moment sustains any longer that hard and soft chancre are in any way related. Who is to decide when such contradictory opinions are emitted by such competent men?

I submit that the evidence must again be laid before the profession, and it must be allowed to take sides, and judge for itself. Discussion is necessary for the interpretation of experience.

In the first place, I maintain that there has been far too much said as to the difficulty of diagnosing between the hard and soft chancre. The number of cases which are obscure are infinitely inferior in number to the simple and evident ones, and the diagnosis, in general, is easily enough made. The guiding points in the diagnosis are the number of the ulcers, their appearance, the condition of the base, that of the glands, and the results of inoculation. As a general rule, the syphilitic chancre is solitary, or at most there may be two, three, or four chancres. On the other hand, the simple chancre is generally multiple. As many as 60 or 70 soft chancres have been noticed in one female patient. This, of itself, will often guide the practitioner in his diagnosis, for if a woman come with a single sore, it will almost certainly turn out to be syphilitic: whilst if another come with 20 or 30 sores, these will be assuredly soft chancres.

The soft chancre is an ulcer, a true ulcer, which is hollowed out of the tissues; it causes a loss of substance; its edges are sharply cut, abrupt, acute, and often burrowing. The syphilitic chancre, on the other hand, is an erosion much more frequently than an ulceration; even in its ulcerated form it is ordinarily less excavated than the simple sore; it has no sharp edges, and only an adherent margin, which is often raised, and forms a circular cup, surrounding a central erosion.

The *base* of the simple sore is unequal, velvety, and anfractuous; its colour is yellowish and of a clear tone; it secretes abundantly, and furnishes true pus. The *base* of the syphilitic sore, on the other hand, is smooth—so much so that, in some cases, it appears as if varnished, glistening and iridescent; its colour is either greyish or reddish-brown, and it has been compared to the colour of muscular tissue. The colour is always darker than that of the soft sore. It secretes generally very sparingly, and its secretion is sero-sanguinolent rather than purulent. It is only when irritated that it secretes true pus.

The base of the soft chancre is like that of an incised wound; it is supple and soft. Occasionally, indeed, the tissues around and beneath the chancre may thicken and become engorged, but the hardness is only that of inflammatory congestion, pasty and œdematous, like the base of a boil. It is also diffused over a certain extent of surface, and is not exactly limited to the base, as it is in the case of the hard sore. In the case of the syphilitic sore, on the other hand, the base is indurated, either beneath the sore or around it; the parchment-like induration is common. The hardness is peculiar in two ways—either in being circumscribed, or exactly limited to the very base of the chancre, and in furnishing a special feeling of elastic resistance, like that of cardboard, parchment, or cartilage, very different from the pasty feeling of inflammation.

In the syphilitic sore there is always some affection of the *glands*. The glands are enlarged to a certain extent, without inflammation, hard, and generally multiple. In the soft chancre, again, there is either complete absence of any glandular affection whatever, or acute bubo—most generally a violently acute bubo. This bubo generally suppurates, and, when opened, turns into a true glandular chancre. In short, when a male patient comes before us with sores on the penis, we may at once diagnose the nature of that sore by examining the groins. If no enlargement of the glands be seen, the sore is probably a soft chancre. If there be an acute, inflammatory bubo, we have a soft sore, and if we have hard, movable, multiple, independent glands, we may consider that the patient has hard sores.

Inoculation may be had recourse to in case there remain any doubt. In the case of the soft sore the inoculation will give on the next day or the day after that a specific pustule. If, again, the chancre be syphilitic, the inoculation will be negative. Inoculations when made should be most carefully watched, and as soon as the information sought is obtained, the pustule should be at once destroyed by energetic cauterisation.

Such are the modern doctrines with regard to the chancre adopted since the writings of M. Ricord were added to by the great work on affections of the skin symtomatic of syphilis, published by his most able pupil, Dr. Bassereau, at Paris in 1852. Ricord, as we know, formerly held the doctrine that the chancre was always a product of one virus, but that it depended upon the health or idiosyncrasy of the person who was inoculated with it whether the sore would indurate and infect the constitution or no.

In this work Bassereau for the first time pointed out that if we confront all patients who have been affected with chancres followed by secondary symptoms with the persons who communicated contagion to them, we find that all such persons, without exception, have been affected with chancres, and then with constitutional symptoms. If, on the other hand, he said, we confront persons affected with chancres which have caused no symptom of general syphilis with the persons by whom they have been infected, we see the latter, without exception, also affected with chancres, the action of which is limited to the point first of all attacked. Thus never does a chancre which is followed by constitutional accidents give rise to a purely local chancre, nor does a local chancre ever communicate by contagion a chancre which will be followed by the universal symptoms of syphilis.

(a) A paper to be read at the Philadelphia International Medical Congress in September, 1876.

Here, then, is a clear statement of the doctrine of the dualism of the chancre, and Dr. Bassereau, in support of these general laws thus boldly enunciated by him for the first time in 1852, was able to confront subjects attacked with syphilitic erythema thirty-four times with those persons who had given them their disease. In thirty-one of these cases the persons who had infected them presented the same symptoms; these had all, without exception, had chancres followed by constitutional accidents. (Aff. de la Peau, par Dr. Bassereau. Paris, 1852.)

In 1856, M. Dron was enabled to collect 111 cases of confrontation, including those of Bassereau, relative to the initial lesion of syphilis, those of M. Clerc relating to the chancroid, and others relating to both varieties, and furnished by Dr. Diday, Rollet, and Fournier. In all of these without exception the type of the ulcer remained unchanged in passing from one person to another. I have myself made as many confrontations as I could easily attain to, and have been long satisfied that syphilitic ulcers and secondary symptoms always arise from contamination with a person himself or herself affected with syphilis. Further investigations under the supervision of M. Ricord, and with the very same result, were made by Drs. Fournier and Caby at the Hôpital du Midi and the St. Lazare Hospital of Paris. Their observations were published in detail by M. Fournier (Ricord's "Leçons sur la Chancre,' 1858, and in a pamphlet, "Recherches sur la Contagion du Chancre," 1857), and they refer to fifty-nine cases of transmission of chancres with thirty-nine of soft sores.

This converted Ricord to dualism. Such are the clinical proofs of the truth of the doctrine called the *dualism of the chancre*, and I must say that nothing I have seen or heard since to the contrary has altered my opinion that M. Bassereau has proved his point.

Not contented with this clinical proof, however, Bassereau has expended much labour to show that syphilis, soft sores, and gonorrhœa had for many years been completely distinguished by practitioners who lived about the year 1500, from which I think all who are capable of being convinced by evidence must admit that syphilis was an entirely new disease introduced into Europe some years before the end of the fifteenth century.

According to Jean de Vigo, writing close upon the time when syphilis first entered Europe, the indurated chancre was even then the type of the ulcer which was recognised as the precursor of the famous pustular eruptions so frequently seen at the end of the fifteenth century. He says:—"Nam ejus origo in partibus genetalibus, videlicet in vulvâ mulieribus, et in virgâ in hominibus, semper fuit cum pustulis parvis, interdum lividi coloris, aliquando nigri, nonnunquam subalbidi, cum caloritate eas circumdante." (De Morbo Gall., lib. v.) Gabriel Fallopius says, too:— "Quoties videtis sanatam cariem, et quod remanent calli circum cicatricem, tenete esse confirmatum gallicum." (De Morbo Gall., cap. xxiii.)

If it be practically demonstrated, as it has been by Bassereau, Fournier, Ricord, and others that a person affected with chancre and secondary symptoms cannot transmit by contagion any but a chancre which will be followed by constitutional symptoms; if it be true that a chancre, the action of which is limited to the tissues on which it is seated, is not capable of engendering by contact anything more than a chancre, the effects of which will also remain entirely local, it is clear that we are compelled to admit two species of chancre which used to be confounded by former writers on syphilis.

It would certainly not be impossible that the local chancre might be only a degenerated true chancre. This fact, if it were demonstrated, would be one of the most certain proofs of the weakening of the syphilitic virus, and ought to give us some hope that the disease may disappear some day or other, a hope which hitherto has been doomed to disappointment, but which was entertained by the physicians of the fifteenth century. No fact, however, with which I am acquainted has shown me that such is the case, although I intend adverting to the views of Dr. Boeck, Dr. Morgan, and Mr. Jonathan Hutchinson further on.

Dr. Morgan's views would even tend to make his readers suppose that gonorrhœa was occasionally one of the products of syphilis, but historically we know quite well from the dissertations of W. Beckett in the "Philosophical Transactions," and from numerous other sources, that contagious discharges were recognised in antiquity and in the Middle Ages. This gonorrhœa was described in England as burning or brenning by John Ardern, who lived about the close of the fourteenth century.

Ulcers of the genital organs are described as well as suppurating buboes in the groin, by all the Greek, Latin, and Arabian writers on medicine. Celsus describes simple, phagedænic, serpiginous, and gangrenous ulcers. Cazenave asserts that these were symptoms of primary syphilis; but there is no record on history worthy of any attention of the existence of general syphilis before 1494. At that time a perfect host of writers narrate the appearance of a *new disease*, at first considered simply epidemic, and then eminently contagious, which was most frequently announced by an ulcer on the genital organs, although this was only the first and slightest part of the disease. First called le Mal Français, it afterwards was named syphilis by the great surgeon and beautiful poet, Fracarter. Thus the physicians of that time were careful not to confound, as was later done, the ulcer of the genital organs, already described by the Greeks and Romans, with the callous and livid ulcers newly seen on the genitals, after which it was no longer suppurating buboes that were seen, but pains in the bones and pustular eruptions which attacked the whole surface of the body.

Alexander Benedictus (Benedetti), writing in 1497, speaks of the ulcerations of the genital organs by which the mal Français commences, the eruptions of which are more hideous than lepra or elephantiasis. He speaks of ulcers on the penis and vulva, and of buboes as diseases already known to the ancients. Syphilis in infants at the breast was first described by Torella in 1498. The Emperor Maximilian on August 7, 1495, promulgated at the Diet of Worms the following edict:—præsertim novus ille et gravissimus hominum morbus, nostris diebus exortus, quem vulgo Malum Francicum vocant, post hominum memoriam inauditus, sæve grassatur. Philip Birvald in 1505, Cataneus in the same year, and many others bore witness to this being a new disease. Antonio Benevieni, a most distinguished physician of the end of the fifteenth century writes:—

Novum morbi genus anno nonogesimo sexto supra mille quadrigentis à Christianâ salute, non solum Italiam sed ferè totam Europam irrupit. Hoc ab Hispaniâ incipiens per Italiam ipsam primum, tum Galliam cæteræque Europæ provincias laté diffusum mortale quam plurimas occupavit. In the same strain, wrote also Beneditti (1496); Gillini (1497); Torella (1497); Montagnana (1498): and a little later, Vigo (1514); Fracarter (1546).

Diez de Isla and Ovieda the historian, give occular testimony of the origin of the disease, which Diez de Isla seems to say came into Europe, from America, on the 4th March, 1493.

(To be continued.)

◆

REVULSIVE LINIMENT.

M. CORSON (*l'Union Médical*) advocates a mixture of croton oil 1 gramme, tincture of iodine 5 grammes, and sulphuric ether 2 grammes. This application limits the eruption on the skin better than when croton oil is employed alone.

ON THE ANALYSIS OF MILK, ON ITS COMPOSITION, AND ON THE QUALITY OF THE MILK SOLD IN DUBLIN AND ITS SUBURBS.

By Ernest H. Cook, F.C.S.,

Associate of the Royal College of Science for Ireland, and Chemical Exhibitioner of the London University.

The frequent prosecutions of milk vendors for the adulteration of their milk, has rendered it a matter of very great importance that the methods adopted for its examination should furnish correct results, for whilst it is important to protect the public against the adulteration of this and other articles of food, it is equally important, as a matter of strict justice, that the vendors are not wrongly punished, owing to the defective methods employed in the examination, or from any other defect on the part of the analyst.

I was induced, at the suggestion of Professor Galloway, to examine and compare some of the different methods which have been from time to time proposed and adopted for the analytical examination of this fluid. The first method I examined was that adopted by Messrs. Wonfor and Pontifex, when they examined the quality of the milk sold in Dublin and the suburbs in the years 1861-62. This method gives correct results, but it occupies a considerable time. Messrs. Wonfor and Pontifex conducted the examination in the laboratory of this institution, and their results and mode of analysis are printed in Vol. IV. of the journal of the Royal Dublin Society.

Professor Wanklyn has recently worked on the subject, and has introduced considerable improvements, but the method he proposes for the determination of the fat I find to be unsatisfactory. I tried several other methods for determining the quality of the fluid, but I found a combination of Wanklyn's process, and the one adopted by Messrs. Wonfor and Pontifex, with some slight alterations in the manipulation, to yield the most accurate results.

The following is the process I finally adopted :—

1st. The density of the milk when performed was determined by direct weighing in the ordinary specific gravity bottle. The specific gravity of skimmed milk is higher, and the specific gravity of milk adulterated with water is lower than that of pure milk. As the lactometer is still very much used to determine the purity of milk, I may here observe that it is a most untrustworthy instrument, as Wanklyn in his work on "Milk Analysis," very satisfactorily proves.

2nd. Determination of the total solids and ash. Weigh out in a small platinum dish about five grammes of the sample, and evaporate on the water bath until the weight is constant. This will take about three or four hours. The loss in weight gives the water. Then ignite until all the organic matter is expelled and weigh. This gives the mineral constituents. The temperature of ignition should not be too high, or a portion will be lost by volatilization. By employing this method the determination of the solids may, with ordinary care, be made to vary less than ·05 per cent. from the true value.

3rd. Determination of the fat. This is the most important process in the whole analysis, and requires especial care. Weigh out into a platinum dish (of rather larger dimensions than that employed for the total solids) about ten grammes of the milk to be examined. Place the dish on a water bath, and when its contents are warm, add about one-fourth of its weight of pure finely-powdered sulphate of lime, and evaporate the whole to dryness, stirring occasionally with a platinum spatula. When dry (which will take about an hour, as it is not necessary that it should be thoroughly dried), powder in an agate mortar, and place in a small flask, removing from the dish and mortar any adhering particles, by adding some pure sulphate of lime, and subsequently incorporating by trituration. Add this mixture to the residue in the flask, then pour into the flask about 15 c. c. of ether, and gently warm by immersing the flask in lukewarm water. Care must be taken to prevent the ether boiling, as the vapour invariably carries away some of the fat. Agitate the flask, and when the gypsum has subsided filter the etherial solution into a second small flask, which has been previously dried and weighed. While filtering, cover the funnel with a glass plate. Wash the precipitate with ether, and continue the washing until a drop of the solution, passing through the filter, when collected on a clean glass plate, and allowed to evaporate, leaves no residue. When all the fat has thus been extracted, connect the flask by means of a delivery tube to a small Liebig's condenser, and proceed to distil over warm water. Care must again be taken to prevent the boiling of the ether. Continue the distillation until the fluid in the flask becomes turbid, then disconnect the flask from the condenser and place it on the water bath, until the fat accumulates in globules. Finally, dry in a closed bath and weigh. The increase in weight is the amount of fat.

The addition of the insoluble sulphate of lime produces a residue which can be readily powdered and easily manipulated. Milk residues obtained without any addition of insoluble salt, are of such a nature that the residue cannot be easily powdered, and the fat completely extracted.

4th. Determination of the caseine and milk sugar. Weigh out into a porcelain dish about ten grammes of milk, and gently warm on the water bath. Then add a little acetic acid (about 2 c.c.) warm, and allow to stand for about half-an-hour. The caseine is thus coagulated, and in coagulating takes the fat globules with it. Collect the precipitate on a tared filter, which has been previously dried in the closed water bath at 212° F., and weighed in a stoppered tube, and wash it with hot water until free from acid. Dry the filter and precipitate in the bath at 212° F., and weigh in the tube as before. Deduct the amount of butter previously found from the butter and caseine, the remainder is the quantity of the latter substance. The filtrate and washings from the caseine and fat are collected and diluted, and the milk sugar which it contains estimated by Fehling's method. The milk sugar may also be determined by difference from the total solids.

Wanklyn gives two methods for the determination of the caseine,—one by direct weighing after the extraction of the fat and milk sugar, the other by determining the amount of ammonia which it is capable of furnishing when treated with alkaline permanganate of potash. Both these methods I tried, but must give the preference to the one I adopted.

"A great deal," Dr. Voelcker observes, "has been said and written about milk adulterations. *Sheep's brains*, *starch*, *chalk*, and *pipe-clay*, which are said (on what authority nobody has ever decided) to have been found in milk, only exist in the imagination of the credulous or half-informed." Milk adulteration resolves itself into one of two things, either the addition of *water* or the abstraction of *cream*. The amount of water and fat can, as I have shown, be accurately determined by analysis, but as the composition of the milk yielded by different cows, and even by the same cow at different seasons of the year, varies, and as the amount and quality of the food exercise an important influence on its composition, it cannot be decided whether the milk has been adulterated or not, unless the adulteration has been considerable, either by the addition of water or the abstraction of cream, for there may be a difference of from 25 to 30 per cent. in the commercial value of pure milk. Another and most important fact, and one which ought not to be overlooked by those who have the carrying out of the Adulteration of Food Act is this, that the constituents of the milk begin very soon to separate in the form of cream, insomuch that in the course of three hours the milk in a sale-can may at the end of that time—where the parties go on selling small quantities for hours—be so impoverished owing to the first portions taking away an extra quantity of fat, that it might be condemned as being adulterated with a considerable quantity of "skim milk," although there has been no adulteration of any kind practised. As there is no chemical difference between the water which may be added and the natural water in the milk, the adulteration or non-adulteration of milk with water is determined by the total solids the specimen under examination contains. The total solids vary considerably in different specimens of milk. Dr. Voelcker, the chemist to the Royal Agricultural Society of England, found in one particular sample as much as 16 per cent., and in another only 9·3 per cent. of solid matter; but, generally speaking, he thinks the usual variations are from 10 to 12 per cent. in good wholesome milk. The fat is the constituent which varies the most. Dr. Voelcker found that the milch cows at Cirencester College yielded in September 1·99 per cent. of fat in the morning, and 1·79 per cent. in the evening. This poverty he attributed to an insufficient supply of food; and in December the cows yielded 3·74 per cent. in the morning and 4·12 in the evening.

Owing to this variation in the composition of pure milk, different standards for the total amount of solids pure milk ought to contain are adopted by chemists. Dr. Tidy, the Public Analyst for the City of London, and other places, adopts 10 per cent. as the standard of purity; Dr. Cameron, the analyst of the City of Dublin, adopts 12 per cent.; and Professor Wanklyn adopts 12·5 for total solids, and 3·2 as the standard for the fat. Professor Wanklyn's standard, both for solids and fat, is, in my opinion, too high; the sample of pure milk (No. 12) I obtained from the Albert Institution, did not, as the analysis shows, contain either the quantity of solids or fat these standards fix as the test for the purity of milk; indeed, Professor Wanklyn in his book on "Milk Analysis," in which he gives this standard, gives an analysis of average country milk, and the amount of fat the milk contained is only 3·07, so that the analysis he gives does not reach the standard he employs.

In determining whether the samples of Dublin milk I examined, the analyses of which I gave, were adulterated or not, I have taken as my standard for total solids 11·5 per cent., the one adopted by Messrs. Wonfor and Pontifex. It may be interesting to show, before proceeding further, what amount of water would appear to have been added to a milk containing 10 per cent. of total solids, which is Dr. Tidy's standard for pure milk, by the standard I have adopted, by the one adopted by the Dublin City Analyst, and by the one Professor Wanklyn employs. By my standard it would appear to have been adulterated with 13.05 per cent., by the Dublin City Analyst's with 16·67 per cent., and by Professor Wanklyn's with 20·0 per cent. of water. These illustrations prove that it is difficult to determine whether a milk is adulterated with water or not, unless a considerable quantity has been added, owing, as I have already stated, to the *natural* variations of the quantity of solids in milk.

The analysis of each sample was commenced on the day it was collected, and all the samples were obtained by trustworthy persons. I am indebted to the kindness of Professor Baldwin for the samples Nos. 12 and 13 from the Albert Institution, and the sample of pure goat's milk, No. 14, was supplied from a private source.

In the eleven samples I obtained from milk sellers, not one contained less than 9 per cent. of solids; out of the twenty samples examined in 1861-62 by Messrs Wonfor and Pontifex, nine contained less than 9 per cent; seven out of the eleven examined by me, and three out of the twenty examined in 1861-62, contained more than 11 per cent. of solids.

Goat's milk is rather richer in solids than cow's milk. Payen gives 14·4 as the percentage, but in the sample I examined they amounted, as shown by the analysis, only to 13·67, proving that the quantity of solids in goat's, as in cow's milk, varies.

The analyses were made in the laboratory of the Royal College of Science.

The results were as follows :—(a)

1.	Water added . . .	4·5	per cent.
2.	" " . . .	20·92	"
3.	" " . . .	14·19	"
4.	Unadulterated . . .	—	
5.	" . . .	—	
6.	" . . .	—	
7.	Water added . . .	4·07	"
8.	" " . . .	18·92	"
9.	Unadulterated . . .	—	
10.	Water added . . .	2·59	"
11.	Unadulterated . . .	—	

Clinical Records.

HOUR-GLASS CONTRACTION OF THE UTERUS.

Dr. **Miles Goodyear**, of Gorton, New York, reports the following very interesting case of hour-glass contraction of the womb. He says :—

On the afternoon of April 17th I was called to see Mrs. C., aged 31; primipara. I found my patient somewhat alarmed because of the severity of the rarely recurring pains. But the patient's fears were easily quieted by a small dose of morphiæ sulph., and by my presence. Pains continued to come on with about the same regularity during the night and morning of the 18th, and at noontime all quieted down, and I returned home. It being the one hundred and sixtieth day only of duration of pregnancy, as calculated from our best data, the womb not presenting the appearance of continuing labour, and the pains being of that snappish kind which seem more characteristic of a "false-alarm" than true labour, it was deemed best to let the patient rest for a time before endeavouring to induce a continuance, even though fœtal life had not been manifest for some time previous. During the afternoon and evening there was some slight pain, but all became quiet when morning came on.

But in the evening of the 19th (after drawing off the water, the os being found somewhat dilated) labour came on in good earnest, and my patient was delivered of a dead child at two o'clock in the morning of the 20th.

All pains now immediately ceasing, and finding the deformity remaining as before labour, and the placenta failing to easily come down, I sought to diagnose a second child by examination per vaginam, when the placenta was found attached at the fundus of the uterus, and it was still quite impossible for me to make out the kind or condition of the body above. There being but little hæmorrhage, only a little ergotin was used, and my patient continued through the day with well-marked pains, some of the time groaning, and at other times sleeping quietly.

At six o'clock on the afternoon of the 20th, Prof. T. Hyde, of Cortland, New York, and Dr. J. Goodyear were requested to meet me in consultation.

Under the existing circumstances it was thought best to make a more thorough examination, which, by special request, was conducted by Dr. J. Goodyear. He found, after removing the placenta, an hour-glass contraction, with an opening or communication, of not more than one inch in diameter, with the other portion of the womb, where could be distinguished another child. By gradual expansion the operator was enabled to bring down a foot, and on traction being made pains came on, the child descending slowly; and it was at the same time noticed that, as this contracted portion would come to the more solubly developed portions of the child, little advancement could be made without resorting to more persistent traction.

(a) The editor is obliged to omit the quantitative details as given by the author, as well as the local addresses of the vendors, as not seeming to be of sufficient general interest to justify publication in these columns.

This kind of advancement continued to be made until this contracted portion came to the head of the child, where, for a few minutes, it seemed entirely to be arrested, when, as if something was giving way, the child made rapid advances by the woman's natural efforts, and was born headless.

Thus our patient was found in the early morning of April 21st, after having been delivered of two separate placentas and two children, with the exception of one head, which still remained in the upper cavity of the unnatural womb. No flooding followed; patient slept some time from exhaustion, and there was but little tympanites. We called in on the morning of April 22nd, and found the head brought nearly down by the organ's own power. No more hæmorrhage than would have been considered safe, but the circulation showed considerable activity with the increasing distention. With a continuance of these symptoms, she died on the afternoon of April 24th.

Query.—Was this a natural hour-glass developed womb, natural in the woman herself?

Pyæmia following Gonorrhœa.

The *Philadelphia Medical and Surgical Reporter* gives a case of pyæmia following gonorrhœa, reported by George W. M'Caskey, as occurring in the service of Dr. James H. Hutchinson, Pennsylvania Hospital.

The patient was admitted, with a history of rigors, bronchitis and diarrhœa, as many as six stools having been passed in the 24 hours preceding admission. When first seen, she presented a condition of considerable fever, severe headache, dry and furred tongue, complete anorexia, and diarrhœa, tympanitis, and tenderness in the right iliac fossa, together with very marked subsultus. There were no *rose spots*, and the mental condition, considering the subsultus, was fair. On examining the chest, dulness was detected posteriorly over the left side, percussion being painful. Moist râles were heard on both sides, and friction sounds on the left, indicating the presence of bronchitis, plumonary congestion and pleurisy. At first the case was thought to be typhoid fever. At one of his visits, Dr. Hutchinson, noticed œdema of the eyelids on the side upon which the patient was lying. On examination of the urine, pus in large quantities was found present, accounting satisfactorily for the amount of albumen discovered. Further examination brought to light the fact that the girl was suffering from a severe gonorrhœal discharge. The nymphæ also were very œdematous, tender, and threatening the formation of abscess. These facts, in conjunction with the absence of rose spots, and the occurrence of rigors in the commencement of the attack, a symptom, which Dr. Hutchinson thinks rarely occurs in true typhoid, led him to diagnose pyæmia. Dr. Hutchinson believes that what is very generally termed gonorrhœal rheumatism is nothing more than pyæmia, of varying degrees of severity.

◆

Vital Statistics.—From the Registrar-General's report we learn that during last week 5516 births and 3552 deaths were registered in London and twenty-two other large towns of the United Kingdom. The mortality from all causes was at the average rate of 23 deaths annually in every 1000 persons living. The annual death-rate was 17 per 1000 in Edinburgh, 26 in Dublin, 21 in Glasgow, and 19 in London. The death-rate was excessive in Salford, where it reached 29 per 1000, Oldham 29, Birmingham 29, Wolverhampton 30, Portsmouth 31, Sunderland 32, Leicester 34, Hull 34, and Norwich 34. Scarlet fever continues fatally prevalent in Portsmouth. Small-pox caused 7 deaths in Liverpool, and 13 in Manchester and Salford. The fatal cases of diarrhœa in all the large towns showed a decline of 142 from those returned in the previous week, and were equal to an averaee of 4·6 per 1000.

The Greenwich Hospital pension of £80 a-year for deputy-surgeons-general of hospitals and fleets, vacant by the death of John Watson, on the 30th of August last, has been conferred on Robert M'Cormick.

REGISTERED FOR TRANSMISSION ABROAD.

THE
MEDICAL PRESS AND CIRCULAR
is published every Wednesday morning. Price 5d. Post free, 5½d.

POST FREE TO ANNUAL SUBSCRIBERS £1 2 6
,, IF PAID IN ADVANCE 1 1 0

⁂ Post-office Orders and Cheques to be drawn in favour of—
A. A. TINDALL, 20 King William Street, Strand, London, W.C.
A. H. JACOB, 23 Ely Place, Dublin.
MACLACHLAN and STEWART, South Bridge, Edinburgh.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIERE, Rue Hautefeuille, Paris—post free in advance, £1 5s. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLMER and ROGERS; Baltimore, by Messrs. KELLY and PIET; Philadelphia, at the *Medical and Surgical Reporter* Office, post free in advance, £1 5s., about six and a-half dollars; or direct from the Offices in this country for the same amount, by International Post-office Order.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 13, 1876.

DR. ANDREWS'S ADDRESS AT THE BRITISH ASSOCIATION.

The annual address given by the President of the British Association is an occurrence which is now looked forward to with great pleasure by all those who take the least interest in the scientific discoveries of the day. Although, perhaps, not quite so startling or so original as some that have preceded it, the present address does not yield to any of them as regards the importance and number of the facts and scientific truths to which it calls attention. There are few members of our profession who will fail to derive both pleasure and instruction from reading this long and admirable review of the latest triumphs of scientific research, but as many of our readers may not have the opportunity of reading it, we propose to notice only those parts of the address in which they will probably feel most interest.

First in place, and therefore first in point of consideration, is the science of astronomy, and we can, with much satisfaction, look upon the work that has been recently done in this department of knowledge. Thus, among other subjects, we are reminded that the mean distance of the earth from the sun was long supposed to have been fixed at about 95,000,000 miles. The accuracy of this number had already been questioned by Hansen and Leverrier when Foucault, in 1862, decided the question by an experiment of extraordinary delicacy. "Taking advantage of the revolving mirror, with which Wheatstone had enriched the physical sciences, Foucault succeeded in measuring the absolute velocity of light in space by experiments on a beam of light, reflected backwards and forwards within a tube little more than thirteen feet in length. Combining the result thus obtained with what is called by astronomers the constant of aberration, Foucault calculated the distance of the earth from the sun, and found it to be 1-30th part, or about 3,000,000 miles, less than the commonly received number. . . . . It remains to be seen whether the recent observations of the transit of Venus, when reduced, will be sufficiently concordant to fix with even greater precision the true distance of the earth from the sun." Not less interesting is the discovery of Huggins that some of the fixed stars are moving towards, and others receding from, our system, and which has been fully confirmed by a careful series of observations lately made by Mr. Christie in the Greenwich Observatory. "Few achievements," remarks Professor Andrews, "in the history of science are more wonderful than the measurement of the proper motions of the fixed stars, from observing the relative position of two delicate lines of light in the field of the telescope." Into the details of this subject, however, we cannot now enter.

Intimately connected with physical astronomy is the department of cosmical chemistry, and consequently, in the latter part of the address we find this science receiving a due share of attention. "Cosmical chemistry," says Dr. Andrews, "is a science of yesterday, and yet it already abounds in facts of the highest interest. Hydrogen, which, if the absolute zero of the physicist does not bar the way, we may hope yet to see in the metallic form, appears to be everywhere present in the universe. It exists in enormous quantity in the solar atmosphere, and it has been discovered in the atmospheres of the fixed stars. It is present, and is the only known element of whose presence we are certain, in those vast sheets of ignited gas of which the nebulæ proper are composed. Nitrogen is also widely diffused among the stellar bodies, and carbon has been discovered in more than one of the comets. On the other hand, a prominent line in the spectrum of the aurora borealis has not been identified with that of any known element; and the question may be asked, does a new element, in a highly rarefied state, exist in the upper regions of our atmosphere? or are we with Angström to attribute this line to a fluorescent or phosphorescent light produced by the electrical discharge to which the aurora is due? This question awaits further observations before it can be definitely settled, as does also that of the source of the remarkable green line which is everywhere conspicuous in the solar corona."

With respect to the applications of science to the useful purposes of life, Professor Andrews's remarks cannot fail to interest those medical men who are engaged in the study of public medicine. "The fuel," he says, "consumed in large furnaces where coal is used, is greatly in excess of what theory indicates; and the clouds of smoke which darken the atmosphere of our manufacturing towns, are a clear indication of the waste arising from imperfect combustion. The depressing effect of this atmosphere upon the working population can scarcely be overrated. Their pale and almost etiolated faces are a sure indication of the absence of the vivifying influences of the solar rays, so essential to the maintenance of vigorous health. The chemist can furnish a simple test of this state of the atmosphere in the absence of ozone, the active form of oxygen, from the air of our large towns. At some future day the efforts of science to isolate, by a cheap and available process, the oxygen of the air for industrial purposes may be rewarded with success. The effect of such a discovery would be to reduce the consumption of fuel to a fractional part of its present amount; and, although the carbonic acid would remain, the smoke and carbonic oxide would disappear. But an abundant supply of pure oxygen is not now within our reach; and, in the meantime, may I venture to suggest that in many localities the waste products of the furnace might be carried off to a distance from the busy human hive by a few horizontal flues of large dimensions, terminating in lofty chimneys on a hillside or distant plain? A system of this kind has long been employed at the mercurial mines of Idria, and in other smelting works where noxious vapours are disengaged. With a little care in the arrangements, the smoke would be wholly deposited, as flue-dust or soot, in horizontal galleries, and would be available for the use of the agriculturist."

And then with respect to organic chemistry the future historians of that science will have to record a succession of beneficent triumphs in which the effects of science have led to results of the highest value to the well-being of man. The discovery of quinine has probably saved more human life, with the exception of that of vaccination, than any discovery of any age; and he who succeeds in devising an artificial method of preparing it will be truly a benefactor of the race. Not the least valuable, as it has been one of the most successful, of the works of our Government in India, has been the planting of the cinchona-tree on the slopes of the Himalaya. As artificial methods are discovered, one by one, of preparing the proximate principles of the useful dyes, a temporary derangement of industry occurs, but in the end the waste materials of our manufactures set free large portions of the soil for the production of human food.

Most of the latter portion of the address is taken up with remarks on the advisability of our great universities giving more attention to, and affording more opportunities for, the cultivation of the physical sciences. A university observes Dr. Andrews, ought to embrace in its arrangements the whole circle of studies which involve the material interests of society, as well as those which cultivate intellectual refinement; and he goes so far as to say that the industries of the country should look to the universities for the development of the principles of applied as well as of abstract science. In this opinion he is supported by the example set us by Germany, and by the excellent results attending the system of university education adopted in that country. In reference to the immense strides which Northern Germany has made in some of the largest branches of industry, and especially in those which give free scope for the application of scientific skill, we are informed that the artificial dyes produced last year in Germany exceeded in value those of all the rest of Europe, including England and France; yet that country, where thirty or forty years ago industry could scarcely be said to exist, had no special advantage for this manufacture, except the training of her practical chemists. Hence the outlay which is incurred by any country for the promotion of science, and of high instruction, will yield a certain return; and we see that Germany has not had long to wait for the fruits of her far-sighted policy.

There are many other subjects on which Dr. Andrews eloquently discourses, such as those in connection with the cruise of the *Challenger*, the progress of meteorological science, and the nature and origin of meteoric iron. Indeed, when we contemplate the rapid progress of the physical and chemical sciences, the great precision and accuracy with which each step in advance is made, and the firm and immovable foundation on which the great truths and multifarious facts of those sciences rest, we cannot help regretting that we are, from the very nature of the problems with which we have to deal, precluded from making a corresponding progress in the science of medicine. But, as Dr. Andrews well remarked in speaking of the North Polar Expedition, there is an inward and irrepressible impulse in man to explore every part of the world, and every department of knowledge, and it is this same impulse which has already done so much for the healing art, and in virtue of which we can take such stock of our present acquirements as shall not be contemptible, even when compared with that which Dr. Andrews has just taken in respect of the physical sciences.

PACKING THE ARMY MEDICAL SERVICE.

A FORTNIGHT since we noted the fact that Mr. Gathorne Hardy's unification scheme, with its "turn out" at the end of ten years, had, at the first public trial of its popularity, attracted only forty-four candidates for seventy-seven places, of whom—we anticipated—not more than twenty-five would be found fit for admission to the service, in which case the War Office would have just one cadet for every three offices which it desired to fill. We were somewhat surprised to find from the list published last week that Mr. Hardy had netted thirty-three men, who were supposed to be as competent for the care of our country's defenders as their fellows, and we were somewhat chagrined that our calculations should have been upset to this extent, although, indeed, half-a-dozen candidates more or less could not alter the evident fact that Mr. Hardy's blandishments had been contemptuously disregarded by the medical profession.

On a survey of the numbers appended to the list of candidates admitted to the service on the recent examination, our surprise vanishes, and we become conscious that the affair is a juggle, and that the War Office has obtained its medical officers on this occasion, as it obtains its recruits at a pinch, not by tempting the best, but by being content with the worst. In the entrance competitive examinations now held, the maximum number of marks which any candidate could possibly obtain was very nearly 4,000, and it has hitherto been an inflexible rule of the department that no competitor should be accepted who did not score at least one-third of this maximum, or as nearly as possible, 1,320—a low enough standard assuredly to catch even the half-competent men. A reference to the official list will show that for the first time Mr. Hardy has been obliged to go behind this rule, and come down to the level of the competitors. The highest number of marks obtained by any of the thirty-three successful candidates was 2,220, and it seems that our anticipation of the number of competitors who would prove their competency was correct, for exactly twenty-five of the men came up to the usual standard, the lowest of them scoring 1,325, or only just above the minimum which would at former examinations have allowed him to enter with "the skin of his teeth."

But below the name of this last candidate, we find those of eight others, none of whom reached the lowest previous standard, but who were taken into the service in spite of their bad answering, simply to remedy, at any cost of efficiency, the anarchical condition into which the service has fallen, and it appears that Mr. Hardy is not hard to please, for he is content to accept the services of men who can make no better answering than about one-fourth of the maximum. We have taken the trouble to ascertain for ourselves at what figure previous War Ministers have placed the very lowest minimum of merit of an army medical officer, and we have for this purpose totted together the marks of the last and worst man for eight examinations during the last five years. We find that that minimum is 1,498, which may therefore be assumed to be the number at which the line has been hitherto drawn. Of Mr. Hardy's thirty-three men, only nineteen reach this figure, and he has therefore secured little more than the bakers' dozen of competent men whom we promised him, while the remaining fourteen of his new men are shown by their answering to be of the class which previous Governments rejected, but which Mr. Hardy finds himself forced to take for want of better.

The War Minister may feel himself happy in having hobbled over the barrier which his unification scheme has erected in the way of army medical efficiency, but he must clearly see that this state of things cannot last beyond the meeting of Parliament, and that it will increase the difficulty of his position when he comes to answer the House, if the same trick be again resorted to to supply the wants of the service. If the lowering of the standard which he has begun be perpetuated, it will make the army still more distasteful to gentlemen and men of ability in our profession than it already is, for it will fill the ranks of the department with men who cannot be expected to be either agreeable brother officers, or capable surgeons. We commend the state of the service at the present juncture to those who will have, as introductory lecturers, the function of advising students; and we put it to them whether it would not be more sensible for their hearers to "bide a wee," and await the reform which must inevitably come if they wait, than to rush into a service which, having been previously distasteful, has now become scarcely creditable.

Notes on Current Topics.

Wrestling.

A FEW days ago the champion wrestlers of France, Messrs. Bonnet-le-Bœuf, Gaston de Lyon, Solomon, Boulanger, and the mysterious l'Homme Masqué, appeared to contest the wrestling championship of England and France, at the Lillie Bridge Grounds. It was the first day of a grand wrestling tournament, the purpose of which was to decide to whom the title of champion wrestler of England and France should rightly belong. It is not our intention to enter into particulars, as the different matches and feats of strength and agility which took place have been described in most of the daily papers, but we wish rather to draw attention to the importance that should be attached to this kind of physical exercise as a means of developing the frame, and of improving the health and strength of those who practise it. Cricketing, football, and rowing are sports that will probably be always in fashion. But although wrestling contests are seldom seen or heard of, except on such rare occasions as those to which we are referring, we are much mistaken if they do not possess many advantages over all other methods of exercising the human frame.

In the first place, there is no other bodily exercise in which the strength of every limb and every muscle of the body, of every thew and sinew, is so generally and so severely tested as it is in wrestling. In rowing, most of the labour is thrown upon the arms, in football and cricketing, upon the lower extremities, whereas in the exercise of which we are speaking every group of muscles in the body, from those in the neck to those in the soles of the feet, is alternately and energetically called into action, and yet with far less strain upon the lungs and heart than what is involved in most other kinds of physical exertion. In other forms of exercise, such as those above mentioned, a limited set of muscles are called into action, and that, too, with the precision and monotony of a machine; but in wrestling we have the contraction of one muscle alternating with the relaxation of another, and this alternate contraction and relaxation not confined to any one part, but extending over the whole body. Although, moreover, the muscles are so generally and so vigorously brought into play, the respective functions of the heart and lungs are much less embarrassed than they are in those exercises in which there is much running, or in which, as in rowing, there is much constraint of posture. This strong and quickly alternating action of all the muscles of the body necessarily keeps up the circulation of the blood, promotes the cutaneous and pulmonary secretions, accelerates the absorption of effete materials, gets rid of superfluous fat, and finally tends to produce that strength, bulk, and fine contour of the muscles themselves, which we see depicted in many of the ancient sculptures, and in some paintings by the old masters, but which we in vain look for in the limbs of the more effeminate youths of the present day. That wrestling, moreover, can be practised at times when other kinds of physical exercise cannot be resorted to, is a circumstance which strongly recommends its more general adoption as a part of our athletic sports.

Nor should we overlook its uses as a therapeutic agent. It may seem strange to speak of wrestling either from a therapeutic or hygienic point of view, but very little consideration will show that when practised in moderation there is much good to be got out of it. Celsus somewhere recommends people who suffer from dyspepsia to exercise their arms, and as the upper extremities and the muscles of the thorax are very prominently brought into play in the act of wrestling, there is every reason to believe that this kind of exercise, if moderately indulged in, might be very beneficial to the health of those youths whose pursuits or studies are of a sedentary nature, especially those who are said to be "growing fast," and whose physical development is almost wholly sacrificed to their mental culture.

There is just now a great deal of talk about public hygiene, or public medicine, as it is with more dignity [illegible]ed, but there is a lamentable lack of individual hygiene so far as it constitutes a part of the prevention or treatment of disease adopted at the present day. We are all apt to be satisfied with prescribing medicine, or at most, a little change of air, totally unmindful that there are others, and perhaps more efficient therapeutic or prophylactic agents at hand; and hence we cannot be surprised if hydropathists, homœopathists, and many other "thists" start up and usurp the cultivation of a field which our apathy or prejudices have allowed to lie barren and unfruitful.

If ever London and other large cities are adorned with such magnificent public baths as the wealth and resources of modern civilization ought certainly to afford, large *gymnasia*, and places especially adapted for wrestling, should form an important part of the buildings erected for the purpose, as the exercise of wrestling could not be indulged in at a better time than after the body has been braced up by a few plunges into the cold bath. We might say a good deal more on the subject, but perhaps enough has been said to show that wrestling ought to form a more important part of the physical exercises of our youth than is at present the case. Perhaps the course of tonic medicines, which we are too fond of prescribing, and to which we often attribute more beneficial effects than they can possibly lay claim to, might be sometimes advantageously replaced by a course of physical training, or of some such athletic exercises as that to which we have ventured to draw attention.

Action of Aconite.

THE valuable researches which Dr. Harley has made from time to time into the physiologial action of many of our most important drugs, more especially "Our Old Narcotics," must be familiar to all who have kept themselves *au courant* with our latest advances in therapeutics. Dr. Harley has recently directed his attention to the action of aconite, and, according to the *Dublin Journal of Medical Science*, he has come to the following conclusions on the subject:—1. Aconite affects a portion of the cranio-spinal axis in the same manner that strychnia affects the whole. It produces an excitement which results in intermittent spasms. 2. The focus of the action of aconite is the medulla, about the roots of the pneumogastric hypoglossal and spinal accessory nerves. Thence its influence radiates along the cranio-spinal axis with rapidly diminishing intensity as far forwards as the centre of the third nerve, and as far downward as the origin of the phrenic. 3. Beyond the limits above indicated, aconite exercises a depressing influence on the cranio-spinal axis almost amounting to paralysis. 4. The action of the alkaloid on the sensory function appears to be co-extensive and co-equal with that on the motor function, the area for intense action having the same limits, beyond which the anæsthesiant action rapidly diminishes in intensity. 5. Apart from the derangement of accommodation, due to spasm or enfeeblement of the muscular apparatus of the eye and the ear, the senses of sight and hearing were unaffected; the latter, indeed, was apparently wholly unaffected.

There was no evidence of any impairment of smell. Taste was, without doubt, greatly disturbed, both on account of its relation to common sensation, and of the deep implication of the fifth nerve. 6. Beyond the slight depression of function resulting in somnolency (after medicinal doses and in the intervals of the paroxysms which follow poisonous ones) aconite has no direct influence on the brain, and the effects produced by asphyxia have usually only a brief duration at the end of a paroxysm, or immediately preceding the death of the animal. The intense distress of impending suffocation produces, however, a total disregard for everything else but the desire for relief, and thus the animal rages frantically about as if actually delirious. 7. The sympathetic nerve is unaffected. At the moment of death the pupils dilate vigorously, and after death the heart may continue to pulsate, or if the right heart be arrested by distension its action may be revived by depletion. The contracted left heart is still only because it is empty. From the evidence adduced, Dr. Harley thinks it conclusively proven that the heart is only secondarily affected, and as a consequence of the respiratory difficulty. 8. Death results from asphyxia and progressive collapse of the lung, the former being due to the spasmodic closure of the respiratory passages and paralysis of the muscles of inspiration, and the latter to paralysis of the muscles of inspiration, and notably of the diaphragm, which is tucked up higher and higher by the intermittent efforts of the upper intercostals, the scalenic, and the sternomastoid muscles.

The Spiritualists and the Balham Murder.

In the *Spiritualist* of August 11th, we find a detailed report of a *séance* with "Dr." Slade, in the course of which the ghost of Mr. Charles Bravo was supposed to write with its own hand—if a ghost can have a hand—the following letter explanatory of the mystery which has puzzled so many minds :—

> Dear Sir,—I am anxious to see my dear and loving wife, and tell her how sorry I am, and how unhappy I am for making her the trouble I have. She was not the one that gave me the poison, or anyone in the house. I *did* it *myself*, and will tell her all about it if she can come here, so I can. I took the poison because I was out of temper, and had a hatred against that bad man, Dr. G. My dear wife did not know anything about it, or her maid. Dr. G. shall never prosper, and shall be made to suffer as I have suffered. Do, for God's sake, send for my dear wife, so I can tell her all. Poor soul, how she has suffered, and all for me. When I tell her how I got the poison, she may tell the same if she wishes, but I must tell her first. Please act on my request, and relieve a troubled spirit.—I am truly, Chas. Bravo.

The puerility of style and disjointed phraseology of this letter are quite enough to show that it never emanated from a barrister or a man of education, unless, indeed, it be a peculiarity of ghosts to be ungrammatical. The only value which such a letter possesses, is, that it suggests the weakness of spiritualism when submitted to the light of an honest test. It would seem from the letter, that Mr. Bravo committed suicide, and that his spirit is in anguish because his wife is suspected of having poisoned him. Why does he not relieve his troubled spirit, satisfy public justice, and relieve his "dear" wife of a terrible suspicion, by giving a word of information which would prove that his death was suicidal. Nothing would be easier. The ghost has only to name the chemist from whom the tartar emetic was bought, and the whole mystery is at an end; and yet neither that information nor the least hint which might throw light on the matter is dropped.

Nothing can prove more perfectly than this, if proof were desired, that the writer of the letter knew nothing about it, and that the pretended communication with Mr. Bravo was a deception and a swindle, and yet there are persons who ought to have sense if they have none, who fail to see that the practical test of spiritualism is its elucidation of such subjects, and that it has always ignominiously failed in the use of the means, which, if they could be employed, would convert the whole world to a belief in it.

Transmission of Measles to the Lower Animals.

An interesting case of this nature is described in a recent report of the Epidemiological Society. A dog licked the hand of a child lying in bed, and on whom the measles eruption was at its height. Twelve days later the dog sickened, and suffered for two days from nasal discharge, and four days later died, with marked congestion of the throat and air-passages. It has been held by some authorities that measles in man is the analogue of distemper in dogs—indeed, it has been urged that they are the same diseases; but this case contradicts such a view, for the dog in question had, four years previously, gone throught an attack of distemper, and although second attacks of the various eruptive fevers are common enough in children, second attacks of distemper are rare amongst dogs, while such second cases, when they do occur, are invariably of a slight and temporary nature.

Treatment of Acute Albuminuria.

In the *Practitioner* for August, Dr. De Haviland Hall relates the experience he gained as Resident Medical Officer at a large dispensary, during an epidemic of scarlet fever (about 300 cases), in which dropsy was a frequent sequel.

At first the patient was ordered the perchloride of iron, and was allowed no solid food except a little bread and milk, and as much water as he liked to drink. The skin was also kept gently acting. If, however, the urine was nearly or altogether suppressed, or if uræmic symptoms appeared, all food was forbidden for two years, the child had nothing but water and a drink made of cream of tartar (℥j. ad. Oj.) in sweetened water with a little lemon-juice. If at the end of this time the kidneys began to act, a little milk was allowed, but not more than a pint in the 24 hours; if, however, the uræmia continued with little or no urinary secretion, the water and cream of tartar was persevered in, and in severe cases nothing else was given for thirty-six hours. Dry cupping mustard poultices over the loins, and a purgative were the only additional remedies ever employed. "The explanation of the good effects of abstention from solid food, and especially meat is, that a patient is entirely deprived of nitrogenous food, the work of the kidney is less, and the urine is rendered less irritating, while the mild diuretic action of the cream of tartar seems to be useful." Dr. Hall also observes that Mr. Churton has reported some cases of puerperal convulsions which were treated by keeping the patient almost entirely on nitrogenous articles of food. After citing a case which was a fair illustration of those he had under treatment, and after quoting the various and conflicting plans of treatment that have been recommended by different authors, Dr. Hall sums up his treatment of acute Bright's disease in the following words:—1. Milk and water with arrowroot; no solid food. 2. Mild diuretics, with a free supply of water. 3. The skin kept just moist. 4. A daily evacuation of the bowels.

An Antiseptic for Meat Preserving.

In the course of some recent inquiries, M. Zöller (of the Gottingen Academy) was led to study the properties of sulphide of carbon as a preserving and disinfecting substance. Beef and veal in quantities of 250 to 1,000 gr., were put under glass jars at temperatures between 15° and 24°—a little of the sulphide being also present—and were kept there 32 days. The meat showed no signs of corruption; it retained its elasticity, and was only altered in colour, becoming slightly pale. The same experiment was made with pigeons and hens, and with equally favourable results. Hot rye and wheaten bread was exposed 14 days in moist air containing sulphide of carbon, and it had not the slightest appearance of mould. Over-ripe plums kept for 182 days just as well—there was neither mould nor putrefaction. Two portions of sugar solution, with a little pressed yeast added, soon went into strong fermentation. One of the fermenting liquors was put under the bell-jar with sulphide of carbon, and after 12 hours the fermentation was hardly perceptible. Urine, also, was not decomposed in a sulphide of carbon atmosphere. M. Zöller purposes further experiments, but thinks he is warranted by those already made in considering sulphide of carbon a powerful means of preservation and disinfection — the more powerful, because, even at ordinary temperature it volatilises; and in an air space containing comparatively but little of the vapour all formation of mould or putrefaction is prevented.

Typhoid Fever at Rugby.

Dr. Wilson, F.S.A., medical officer of health for the Warwickshire combined sanitary authorities, has, at the request of the Local Government Board, published a long report on the causes of the cases of typhoid fever which occurred in the Rugby urban sanitary district during the quarter ending 30th June, and on the relation which the fever exhibited to defects in drainage and other means of filth disposal, or to impurities in the water service of the district. "There was, however," remarks Dr. Wilson, "no grounds for believing a general pollution of the public water supply had any share in the cause of the fever, nor could it reasonably be inferred that it had been due to any large extent to sewer air which had been tainted with the poison of typhoid fever." At the same time also, Dr. Wilson does not doubt that the influx of sewer air not specifically tainted was the cause of the majority of the cases which occurred during 1874 and the first half of 1875, and this was owing to badly flushed and imperfectly ventilated drains. Great stress is also laid upon the effects of polluted well-water, and so impressed was the reporter with the danger of using well-water in several towns with drains ramifying in all directions, "that he has no hesitation in recommending that every well should be closed where a public supply can be obtained." With respect to non-fatal cases of this fever many had not come to his knowledge, and it was his opinion that until householders were compelled by law to inform sanitary authorities of the existence of infectious diseases preventive measures and checks would prove futile.

The Austrian General Medical Congress.

The second general congress of the Austrian profession terminated at Vienna on the 2nd of August. Among the questions treated of were those of the organisation of the medical body, of its reports, and of the public health, of fees, of the necessity of a proportionate representation of the medical body in the legislative assemblies, &c. At Gothenburg (Sweden) in the assembly of the Scandinavian profession which took place, the question of making vaccination obligatory in Scandinavia was debated. All the orators spoke in favour of the measure, vaccination being the most efficacious preservative known against small-pox, and recommending that the Government shall order its rigorous enforcement.

Death of Lallah Rookh.

In Tasmania died, towards the end of April in the present year, Lallah Rookh, the last of the aboriginal race, at the age of seventy-three years. She was the wife of King Billy, who died in 1871. She was christened Trucaminni, but the natives called her Lallah Rookh. With her has disappeared the last of the native Tasmanians.

A Lady Graduation in France.

A great crowd assembled a few weeks since, says *La Liberté*, in the large amphitheatre of the Ecole de Medecine of Paris. The greater number of those present were spectators come to see Madame Franceline Ribard take out her diploma of doctor. Madame Ribard entered the hall clothed in a black dress and white collar, and seated herself, while waiting her turn, in an arm-chair which was placed for her. She is a fair woman, intelligent looking, aged twenty-seven years, and the mother of two children. She rose as her name was called, and for more than an hour continued to answer all the questions of the examiners, Messrs. Gavarret, Gubler, Dieulafoy, and Lécorche. She appeared a little confused at first, but soon recovered herself, and her answers were marked with the stamp of confidence and perfect clearness. The thesis which Madame Ribard had sustained with much credit to herself was upon tapping of the eye in the different affections of that organ, especially in detachments of the retina. The jury who examined her declared at the end of the trial that she merited the diploma of doctor, and the president congratulated her warmly on the extent of her knowledge.

Central London Throat Hospital.

The building for which the foundation stone was laid in the early part of this year by Madame Adelina Patti, is now completed exteriorly, and is a substantial-looking building for the purpose for which it is assigned. The interior is also far advanced, and wards will shortly be opened for the reception of in-patients. The ventilation appears to be of a very perfect character, and the heating of the building will be by means of hot-water pipes. Hydrants are also provided on every floor in case of fire.

Social Science.

AMONG the questions down for discussion at the Social Science Congress to be held at Liverpool, the 11th to 18th of next month, are the following :—In the Health Section—What is the best method of making provision for the supply and storage of water (*a*) in large towns as Liverpool and Manchester, (*b*) in groups of urban communities of lesser size, such as exist in the manufacturing districts of Lancashire and Yorkshire ? What amendments are required in the legislation necessary to prevent the evils arising from noxious vapours and smoke ? How can professional and technical instruction be best incorporated with a sound system of general education ?

Suicide in the Clare Lunatic Asylum.

A PATIENT in this asylum, named James Beaky, aged about thirty years of age, committed suicide on Tuesday week by strangulation. The unfortunate man was only admitted to the institution about ten days ago, and we believe showed few, if any, symptoms of a tendency to commit suicide. On Tuesday night he succeeded in secreting his suspenders about his bed clothes, and by their means hanged himself to the gas-pipe about seven feet high from the floor.

The Death-rate of Foreign Cities.

THE annual rates of mortality, according to the Registrar-General's most recent weekly returns were in Calcutta 24, Bombay 29, Madras 38 ; Paris 30 ; Brussels 26 ; Amsterdam 25, Rotterdam 27, The Hague 33 ; Copenhagen 32 ; Stockholm 32 ; Christiana 22 ; Berlin 39, Hamburg 32, Breslau 54, Munich 39 ; Vienna 26 ; Buda-Pesth 43 ; Rome 20, Naples 35, Turin 22 ; Alexandria 51 ; New York 34, Brooklyn 32, Philadelphia 26, and Boston 33. Typhoid fever caused 78 deaths in Paris, against 87 and 82 in the two preceding weeks. Diarrhœal diseases caused the high death-rates in Berlin, Breslau, and Buda-Pesth.

Statistical Society.

THE following is the title of the essay to which the Howard medal will be awarded in November, 1877. The essays to be sent in on or before June 30th, 1877 :—"On the condition and management—past and present—of the workhouses and similar pauper institutions in England and Wales, and their effect on the health, intelligence, and morals of the inmates." Further particulars or explanations may be obtained from the assistant secretary, at the rooms of the Statistical Society, Somerset House Terrace (King's College entrance), Strand, London, W.C.

Lead in Vegetables.

DR. DE LOOS, of Leyden, writes that he was consulted regarding certain symptoms of paralysis and nervous disturbance which suggested the idea of lead poisoning. The symptoms occurred in a family residing in the neighbourhood of the place where a manufactory of white lead had stood twelve years previously ; they made use of vegetables growing on the spot. In order to make it certain that the poisoning was produced, as he believed it to be, by the vegetables, Dr. de Loos examined chemically some red beet, endive, and carrots, and ascertained the presence of lead in all. In a beet weighing 650 grammes he found the equivalent of a centigramme of metallic lead ; in another of about the same size, 11·3 centigrammes ; in six carrots, weighing altogether 272 grammes, there were 1¾ centigrammes of metallic lead ; and the metal was also found in the endive. The ashes of the plants also contained traces of copper, which had probably existed as an impurity of the lead.

THE total amount received towards this year's Hospital Saturday Fund up to the end of last week, was £2,750.

THE enormous quantity of one and a quarter million gallons of cod-liver oil has been shipped from Newfoundland during the present season.

DR. TONER, of Washington, has offered to give the profession of Pittsburg a library of medical and scientific works of the value of $20,000, and a sum sufficient to secure to the library an annual lecture on medical and scientific subjects.

AT the Social Science Congress to be held in Liverpool in October, there will be an exhibition of sanitary inventions, appliances, &c. Intending exhibitors must communicate at once with the Secretary of the Association in London, in order that space may be granted to them.

THE Keighley guardians, having been released from gaol on Saturday, left Leeds for their homes amidst a popular demonstration of approval for their defiance of the law. A similar demonstration awaited their arrival at Keighley, when the train drew up.

A "WOMAN'S NATIONAL UNIVERSITY" has been established in Washington, "to afford to women a thorough knowledge of science, divinity, medicine and law, both in theory and in practice." Professors of law, medicine, language and social culture have been chosen.

IT is stated that a Washington doctor has actually made a contract for the erection of a furnace for the burning of his own body after death, and also those of any others who may desire this luxury. It is said applications come all the way from Boston for the right to be burned in the apparatus.

AFRICA, following in the wake of European nations, is to have an International Exhibition, which it is proposed to open in February next. There will be a section for medical and surgical works, instruments, chemicals, &c., Capetown being the place chosen for the erection of the building.

AT Kilrush, a man named Patrick Loregan, bone setter, was committed for trial last week for manslaughter. It appeared that a man had fallen from a cart and injured his arm. Loregan was called in and said it was broken. He set it and bandaged it. Three or four days afterwards, when a medical man was called in, it was found that the arm from the shoulder downwards was in a complete state of gangrene or mortification. The arm had not been broken. The gangrene was sworn to have been caused by the tight bandaging of the arm.

THERAPEUTICAL AND SANITARY PREPARATIONS.

Magnesium Citrate.—Messrs. Kinmond and Co., of Leamington, under the name of Magnesilyne, furnish us with an efficient aperient saline salt. It is compounded of carbonate of magnesium and citric acid, which dissolve with a brisk agreeable effervescence.

Salicylic Soap..—Messrs. Tidman and Son have produced an elegant article in the way of soap, which contains an appreciable quantity of salicylicate of potash in combination with other ingredients, and which render it antiseptic. This will prove useful in the sick room, as well as for domestic purposes. It mixes readily with the hard water of the New River Company.

Eucalyptus Oil Soap.——Messrs. Whitaker and Grossmith have also manufactured a soap having somewhat similar claims. It is called "The Eucalyptus Oil Soap," and is vouched for as a sanitary purifier or disinfectant. It is an elegant toilet soap of most refreshing fragrance, and may prove a valuable addition to the sick room and nursery.

◆

Obituary.

DR. DENNING, OF SLIGO.

We have to announce the death of this gentleman on Wednesday morning, the 30th ult. Although he had been ailing for some time, his death was rather unexpected. The deceased gentleman was known as a kind-hearted, amiable man.

DR. SCRAGGS, OF CLOGHER.

We announce the death of this gentleman, a very old inhabitant of Clogher. He was for twenty-four years medical officer of Clogher Dispensary, having only a few months ago resigned that office through the partial loss of his sight, combined with bodily weakness. On Wednesday evening the 30th ult., he retired to bed quite well, and in a few minutes afterwards he was found lying insensible. Medical aid was procured, but without avail. He was seized shortly afterwards with an attack of paralysis, which proved fatal. He expired shortly after three o'clock on Friday, 1st September, being at the time of his death free from all pain.

◆

Literature.

THE STUDY OF PHYSIOLOGY. (a)

Dr. Carpenter's large work on human physiology is so well known to the profession, and its great merits have been so frequently and so generally acknowledged, that there is, on the appearance of this eighth edition, very little to be said in the way of ordinary criticism. We need scarcely observe that the present edition maintains the reputation which the author has gained for putting, as Dr. Johnson would say, into his work as much as it could hold, and for conscientiously placing before his readers the latest results of physiological research. The re-appearance, however, of such a bulky work suggests the propriety of making a few remarks on the study of physiology in our medical schools, especially at a time when so much is said about the necessity of gaining a practical knowledge of that science in the laboratory rather than from books.

That the legislative restrictions which have been recently put upon vivisection will have, in this country, a permanent effect in damping the enthusiasm of our practical physiologists we have every reason to believe, and we fear that they may check that laudable zeal for original research, without which no science can make much progress. But there are many grave reasons why the importance of practical physiology to medical practitioners should not be over-rated, and why the great majority of students will always have to derive most of their knowledge from such works as that to which we are now drawing attention.

With many it has been a matter of regret that human physiology is not taught in our schools in the same manner as anatomy is taught; and only about five years ago Professor Huxley, for whose opinions we all have so much respect, gave expression to this regret in language that could not be mistaken. "I cannot understand," he said, "why physiology should not be taught with the same definiteness and the same precision as anatomy is taught. And you may depend upon this, that the only physiology which is to be any good whatever in medical practice, or in its application to the study of medicine, is that physiology which a man knows of his own knowledge, just as the only anatomy which would be of any good to the surgeon is the anatomy which he knows of his own knowledge." But with all due deference to the opinion of so eminent a *savant* as Professor Huxley, we venture to take exception to the propriety of these remarks, and think that his view of the subject cannot be accepted without much reservation.

In the first place, Professor Huxley himself gives one of the best of reasons why physiology "cannot be taught" in the same practical manner as anatomy, when he admits that "it is a comparatively easy matter to learn anatomy and to teach it; it is a very difficult matter to learn physiology and to teach it." In one science we have to deal with structure and the relative position of parts only; in the other we have to do with the more recondite and difficult subject of function. It is not impossible for a diligent student to see during his pupilage with his own eye, and to dissect with his own hand, almost every muscle and artery, and vein and nerve of the human body. On the other hand, he could not in his whole lifetime perform one half of the experiments by means of which the multifarious facts of physiology have been discovered. The very few years he can spend at the hospital, the number of subjects which during that period must necessarily engross his attention, and the time and labour that are required for demonstrating on living animals, even the more important functions of the animal economy will be always obstacles in the way of the student knowing that physiology which some are able to know "of their own knowledge," or of his ever being able to study that science in the same practical and original manner as he can the science of anatomy. Nor, as respects the future practice of his profession, can so much importance be attached to a thoroughly practical and experimental knowledge of physiology as to a similar knowledge of anatomy. Not only must the latter science be the foundation of all other medical knowledge, but without it the practice of surgery and medicine would be nothing less than charlatanism and guess-work. It is quite different with physiology. A man may be, and many a man has been, a most skilful physician without knowing any more of that science than he has picked up from books. A physician may show great tact in diagnosing a small cavity in the lung, or in managing a pleurisy, without ever having examined the microscopic structure of that organ, and without ever having ascertained or ever knowing that a healthy man exhales from his lungs every hour 1,346 cubic inches of carbonic acid gas. When, in the reign of William III., the famous Dr. Radcliffe put all the court physicians to shame by the prompt manner in which he pointed out to them the true nature of the queen's fatal malady, his knowledge of physiology was probably very slight. And even within the last fifty years many very eminent men have given splendid contributions to the advancement of diagnostics and pathology, who during their pupilage never so much as performed or witnessed a single physiological experiment.

(a) "Principles of Human Physiology." By William B. Carpenter, M.D., F.R.S., &c. Edited by Henry Power, M.B. Lond., F.R.C.S. Eighth Edition. 1876.

Do we then, it may be asked, deprecate the desire of our teachers to give to the study of physiology a more practical shape than it has hitherto taken, the establishment in our medical schools of physiological laboratories, and the use of such an admirable work as that just brought out under the editorship of Klein, Burdon-Sanderson, and other eminent physiologists? Certainly not; we rather hail the new impetus which is being given to the practical teaching of physiology as the advent of a new era both in the study and in the advancement of that science. If practical physiology must yield to practical anatomy in an utilitarian point of view, it undoubtedly far transcends the latter science in the number and interest of the subjects with which it deals, and in the high and varied mental abilities and unwearied powers of research which its successful study entails. Too much pains, therefore, cannot be taken to give to our future physiologists the opportunity of thoroughly and practically grounding themselves in the first principles of that science which they have selected for their special study. Besides, it has always been a legitimate boast of our medical schools that they have afforded the best and sometimes only arena for the successful prosecutions of those branches of knowledge which are auxiliary to the study of practical medicine, and that they have been the birthplace of some of the most splendid reputations that have been earned in the field of natural science. It is no small boon to the poor student coming up to London from the provinces that he can find a congenial soil in which his particular taste can receive proper cultivation, and his abilities abundantly ripen and bear fruit—schools where he who wishes to study chemistry can handle the blow-pipe and the test-tube under the eye of the most eminent chemists of the day, or where he who has a taste for physiology can, in the laboratory of a Rutherford or a Burdon-Sanderson, himself watch the action of the heart in the living frog, or demonstrate all the phenomena of reflex motion.

At the same time, we have to bear in mind that the object of our medical schools is not to make men great chemists, or great botanists, or great physiologists, but to give them a sound and practical knowledge of the profession they have adopted. The advancement which has been made within the last few years in all departments of medicine is so great, and the knowledge which is now indispensable to the practitioner is so much more extensive than it formerly was, that four years are now too short a time for his medical education, even were that confined to the study of anatomy, medicine, and surgery only. It is, therefore, questionable whether too great inducement should be held out, and still more questionable whether the student should be compelled to acquire as thorough and as practical a knowledge of physiology as he should have of anatomy or medicine, inasmuch as the more we raise the standard of medical education with respect to the collateral sciences, by so much we lessen the opportunities of acquiring a thorough and practical knowledge of medicine, surgery, midwifery, toxicology, and hygiene, to the study of which much too short a time is even now allotted at all our medical schools.

And now, to draw our remarks to a conclusion, it is in consequence of the above views and reflections that we are induced, even in these days of physiological laboratories and vivisection experiments, to recommend to the medical student the perusal of such a bulky treatise as that of Dr. Carpenter's "Principles of Human Physiology," provided, however, that he has first impressed upon his mind a firm outline of the subject by the use of a more elementary work, and provided also that he does not merely use it for the purpose of "cramming" for a University examination. We know that the great size of this treatise has always been a great objection to the generality of students. But we do not see, for instance, how the young physician or general practitioner can treat a disease of the stomach, or a disease of the brain, with judgment or success unless he is previously acquainted with *all* and the *latest* knowledge we have respecting the functions of those parts; and we do not see how he is to acquire that knowledge unless he devotes a portion of his time to reading such a repertory of physiological science as that which we have taken as our text for the foregoing observations.

A TREATISE ON GOUT AND RHEUMATIC GOUT. (*a*)

THIS well-known work has been for several years out of print, and its reappearance in its present form will be welcomed by the profession. This edition bears ample evidence that during the interval Professor Garrod has been working hard at the subject with which his name is so closely associated. Such being the case, though the earlier editions have been noticed here, this edition calls for a comprehensive review.

The work commences with an account of the views held about gout by the ancients, and Hippocrates certainly knew it well, both as to its diagnosis and its treatment. That he held it to be due to the "retention of humours" showed that he recognised its causation. But what those humours were remained comparatively unknown till Dr. Garrod clearly demonstratad that the *materiis morbi* was uric or lithic acid. From that time the treatment of gout acquired precision, and the purgings and cooling agents of the old Greek took definite form. Doubtless a fairly accurate treatment had been arrived at empirically, but it was the discovery of the "humour" which gave precision to the therapeutic aim. In 1847, a patient in King's College Hospital, labouring under gout in an acute form, was blistered, and the serum examined with the result that uric acid was readily found by all its tests, the most satisfactory being the immersion in the serum of a fibre of thread which became encrusted with uric acid crystals. A table of forty-seven cases follows, which clearly proves "that the blood in gout is invariably rich in uric acid." At the same time that the blood of the gouty is rich in uric acid, and that waste product is but imperfectly eliminated by the kidneys. The following case, presenting no unusual features, shows this well:—

"Case 10.—W. F., a male patient, aged 38, has had several attacks of gout, at first implicating only the ball of the great toe, but afterwards affecting the joints of both upper and lower extremities; a few spots of urate of soda seen on the palmar surface of the left index-finger. No active symptoms present when the urine was submitted to examination, and no medicine taken at the time.

"May 11th, 1854.—Urine, 35·5 fluid ounces; sp. gr., 1024. Acid; no deposit; no albumen. Uric acid in 24 hours, 1·34 grains; urea, 306 grains.

"May 15th.—Urine, 39·5 fluid ounces; sp. gr. 1018. Acid—uric acid in 24 hours, a trace only; urea, 338 grains. Blood found to contain much uric acid."

(*a*) A Treatise on Gout and Rheumatic Gout. By A. B. Garrod, M.D., F.R.S., Consulting Physician to King's College Hospital, late Professor of Therapeutics at King's College.

During the time of an attack the amount of uric acid is distinctly increased. For instance, in Case 3, "J. C.. a male patient, aged 57, suffering from acute gout in the ball of both great toes, and in several other joints both of the upper and lower extremities. A few nodules of urate of soda found in the ears, but in no other part of the body.

"May 2, 1856.—Urine, 24 fluid ounces; sp. gr., 1024, at 60° Fahr; turbid from urates, but clearing with moderate heat; it contains a distinct trace of albumen. Uric acid in 24 hours, 3·76 grains; urea, 3·20 grains. The blood of the patient contained much uric acid."

The effect of an attack of gout is thus to clear the system. Often a gouty condition, or lithiasis, lurks unmanifesting till an accident brings it out. This is well shown in the following case:—"A gentleman with a strongly marked hereditary predisposition to gout hurt his knee by a fall when hunting; the pain was not very severe at first, but in the course of a few hours became intense, much more so than could be accounted for by the nature of the injury. It soon, however, became evident that the joint was affected with acute gout, which was speedily relieved on the ball of the great toe of the same side becoming inflamed." This is no uncommon case in practice.

The morbid anatomy of gout is found in the changes which go on in different tissues, especially in the articular cartilages. At Fig. 13 is shown the great toe of a man who had one attack of gout thirteen years before death. Distinct points of urate of soda are to be seen. Other like cases are recorded. At first no real structural injury is done to the parts by the deposit of urate of soda upon them. This is shown by the woodcut at p. 191. "Fig. 17 represents the ends of two metacarpal bones, one incrusting with urate of soda, the other freed from the deposit by the action of warm water, and exhibiting the cartilage apparently healthy in structure." After repeated attacks the joints become enlarged, stiff, or anchylosed, and deformed by the presence of masses of urate of soda. The helix of the ear, too, is a favourite spot for the deposition of urate of soda. The observations of Dr. Todd as to the changes in the kidneys are carrried out here. In very advanced cases of gout the kidneys are found contracted and shrivelled, but Dr. Garrod thinks he can "show that even in the slighter forms and early stages of gout the renal organs sometimes become seriously implicated." The asssociation of gout with imperfect renal action is now generally admitted.

As to how far the skin can and does give off urate of soda is not determined satisfactorily yet, and Dr. Garrod does not quite endorse the views of Petit and Henry, who found urate of soda in the skin of the hand of a man subject to chronic gout. Then as to the causes of gout. Hereditary predisposition is unquestionably a strong factor. Then there is the temperament. "In general terms it may be said that acute sthenic gout occurs most frequently in subjects of a sanguine temperament and those inclined to corpulency; whereas the asthenic and irregular forms are usually seen in individuals of a nervous temperament and spare habit of body."

The use of fermented liquors as a great cause of gout is strongly insisted upon. Then comes the influence of solid food in causing gout. "Piecrust and sweet substances are probably injurious rather from the indigestion they produce than from containing any very noxious substances." "The subjects of gout and calculous diseases are generally persons who live well and eat largely of animal food." Dyspepsia and bilious conditions are often causally related to gout, and often lead to a deposit of urates in the urine on cooling. Study and mental anxiety lead to gout, and often cause it to be persistent. Race goes for little, climate and season for less. The influence of lead is very marked, and Dr. Garrod has found that gouty persons are exceedingly sensitive to lead, so that the mechanical use of lead has often induced attacks of acute gout.

Of the exciting causes he enumerates alcoholic beverages, dyspepsia, cold and moisture, mental or bodily labour, or anything which may lead to marked general depression.

He divides gout into *Regular* and *Irregular Gout*, and says, "Some objection may perhaps be made to the use of the terms regular and irregular gout, and it may be asserted, perhaps with truth, that its so-called irregular manifestations are in fact quite as regular as the articular affection." This is an important statement in several ways. It first teaches that the irregular manifestations of gout, the thousand forms which experience and observation alone reveal, are as regular in their return as the forms we regard as regular gout. This is a matter in which it is desirable that the practitioner hold clear impressions. Bronchitis, dysmenorrhœa, neuralgia, skin eruptions, fits of mental irritability, with sleeplessness—the less-known and so-called irregular forms of gout are just as periodic in their presence as the forms recognised as regular, indeed as inflammations of the articulations themselves. He next tells us that these irregular manifestations are associated with the same poison as the regular forms, and therefore that in all of them the gout, rather than the particular manifestation, is to be treated.

Chapter IX. is devoted to a consideration of the close relationship betwixt gout and uric acid, which is demonstrated in a very clear manner; after which the views of different writers, as Cullen, Sir C. Scudamore, Dr. Gairdner, and others are examined, and then the author gives his own views. He states that gouty attacks may to a certain degree be curative, but that they are liable to do local mischief, and therefore can be treated with advantage. His opinion of the treatment of gout is as follows:—Acute gout is controllable by remedies, both as to the duration of the paroxysm and as to injury done to joints. Secondly, chronic gout is also fully under the control of the physician, and appropriate treatment will give relief, limit further mischief, "which is so prone to ensue if the disease be allowed to run its course, or be recklessly tampered with." Thirdly, gout is apt to return and grow more severe if not met by proper preventive measures. Consequently, we find Cullen's aphorism of patience and flannel strongly condemned, as it certainly richly deserved.

As to the treatment of acute gout, diet is a most important matter. Patients who used to suffer for weeks on a diet of animal food, on a proper dietary got relief in a few days. Any one who has had acute gout will readily endorse this statement. Non-nitrogenised foods, slops, no malt liquor, and but little alcohol in any form is desirable. The patient should keep quiet in bed. Purgatives are useful; for the asthenic a warm pill, for the sthenic salines, Püllna or Carlsbad waters. Mercurials are to be avoided. Diuretics and diaphoretics, especially forms of potash, are good; while anodynes and narcotics are often necessary; opium is not desirable, and henbane or belladonna are to be preferred. It is somewhat odd that Dr. Garrod does not refer to the tincture of hop either affirmatively or negatively, simply ignoring it. And yet Scudamore believed in it, and in dram doses at bedtime, especially with half a drachm of bromide of potassium, the writer has found it very useful and effective. Blood-letting and leeches are strongly deprecated. "Blisters are of most advantage in cases of gout of an asthenic character, when the inflammation has a tendency to linger in the articulations and cause effusion." The local application of warmth and moisture is advocated, and these applications may contain belladonna, morphia, or aconite with advantage. Cold should never be used, and its local application is fraught with the greatest danger. Cotton wool covered with oil silk is often most useful.

Colchicum is examined at great length, both as to its action and utility. It appears that it does not increase the amount of urine solids excreted, rather the other way. Indeed, its *modus operandi* "is still a subject for inquiry, and well worthy of the attention of the therapeutist." Its usefulness, however, is incontestable. It is taken in different forms with, and also without, medical advice. In acute gout it exercises a specific power, and should be continued in decreasing doses after the inflammation has subsided. When great depression is produced by it the gout is apt soon to return. It is also useful during the intervals and in chronic gout. White hellabore is sometimes used instead of colchicum. Laville's well-known tincture is examined and pronounced to "act very much in the same way as a large dose of colchicum." Those who have taken much of the preparations are in time considerably weakened, as is the case after long acquaintance with colchicum in other forms, and often gouty people in time bewail the relief colchicum furnishes, and the recklessness induced thereby.

Chronic gout may be associated with the state of the skin, disturbance in the digestive organs, an augmentated formation, as well as defective secretion of uric acid. In treating each case its relations have to be carefully ascertained for the treatment to be successful. Iodide of potassium, especially with guaiac, is very useful. Guaiac is very good in asthenic gout. "In some its action is almost magical." Serpentary and sulphur are also of service. "The undue formation of uric acid will be found to be especially influenced by diet and regimen, whereas its deficient excretion is more under the control of remedial agents." The persistent following out of a proper line of treatment is shown to be essential in so chronic a malady. Alkalies are indispensable, especially potash and lithi. Dr. Garrod (agreeing with Von Schroff of Vienna) advises, too, the phosphate of soda. Free dilution of the alkalies is recommended. They should be taken on an empty stomach and before food. Large doses of soda salts "favour the deposit of urate deposits." The leaves of the common ash form an infusion of great value. Hot water freely taken does much good in some cases. Stomachics and tonics are very useful in atomic gout; as also are quinine and iron. Where there is albuminuria, counter-irritation over the kidneys, together with hot baths, is indicated. The local application of potash is recommended; friction and passive motion are often of service. Lithia is useful. But of all things a properly regulated dietary is the most essential. Brown meat should be taken in but small quantities; fish, fat, and stewed joints, with farinaceous preparations, should form the bulk of the diet. Good wines and malt liquors are to be eschewed, or taken at the patient's peril. Milk is very good. Exercise, fresh air, and suitable warm clothing are ever desirable. A warm climate may be indicated. The bad effects of mental anxiety are described truthfully. Sudden emotion will bring on gout, and mental anxiety will protract an attack very markedly.

Mineral waters, as Vichy, Wiesbaden, Baden-Baden, Carlsbad, Homburg, Wildbad, and Teplitz are all useful. Buxton is a capital place, both as to water and climate. Aix-la-Chapelle and Aix-les-Bains, Luchow and Barèges, suit others. Chalybeate waters often do much good in the convalescence.

The different manifestations of irregular gout in the different organs occupy a chapter, from which it is simply impossible to make an abstract or take extracts. The diseases to which the gouty are liable are gravel, calculus, lumbago, sciatica, phlebitis, and diabetes. Diabetes often alternates with gout, and during the diabetes there is no attack of gout. Both are diseases of imperfect oxidation, and their association causes no surprise. It is a matter of question if such diabetes is very serious. Lead-poisoning is commonly found in gouty persons. As to prognosis, an attack of gout is a warning to a man to alter his ways; and if old habits are kept up, mischief will follow, which may be kept off if a proper rôle be maintained.

Rheumatic goet is not a blend of gout and rheumatism, but something distinct and *sui generis*, It is closely associated with debility, and its treatment must ever be restorative. It may be very localised, or may involve the articulations generally. Its morbid anatomy was carefully studied by the late Dr. R. Adams, of Dublin, whose descriptions admit of no improvement. It is not so associated with hereditary, age, or sex as gout, and is common in women. It is not confined to those who take alcohol. It is found along with skin affection not uncommonly. "It is a much easier task to prove what rheumatised arthritis is not, than to prove what it is. It appears to be a peculiar form of mal-nutrition of the tissues of joints, accompanied with defective powers." The treatment closely resembles that of atonic gout both generally and locally. Guaiac, arsenic, iodine, iron, and cod-liver oil are all of value. Mineral waters and baths are often useful, but baths may be taken to excess and so do harm. The diet should be nutritive, and stimulants, even malt liquors are not contra-indicated entirely. The diagnosis is given elaborately. The work concludes with the sentence, "Some time ago I was inclined to take a very desponding view of the amenability of this disease to treatment, but year by year I have become more hopeful, and I have frequently seen patients who I feel sure if they had submitted themselves to a rational course of steady restorative treatment, instead of being led by the solicitations of injudicious friends and empiricising advisers to give themselves up to every form of quackery, would have been restored to health instead of becoming, as many of them unfortunately do, miserable and incurable cripples." There is a useful table of mineral waters with their analyses added as an appendix.

The work is one which we heartily recommend to all members of the profession, especially to those who are in good practice. The plates and woodcuts are good, except the cut at page 147.

◆

THE COUNTRIES OF THE WORLD.

THE first part of a new work under the above title has made its appearance from the publishing house of Cassell, Petter, and Galpin. It is intended to form, when completed, a companion treatise to "The Races of Mankind," by the same author, Dr. Robert Browne. If the first number be a fair specimen of the literary and pictorial work of the whole, there can be no doubt as to its popularity. The habits and customs of the remotest peoples and countries, the latest territorial discoveries, deep-sea soundings, &c., are promised, and we look forward to succeeding parts with interest, and wish the work the success it deserves.

CONTEMPORARY AND CURRENT LITERATURE.

The Practitioner for this month contains, as usual, several articles of interest. The one from the pen of the editor, "On the Action of Alteratives," is of considerable practical value. Dr. Faber continues his important contribution "On the Influence of Sea Voyages on the Human Body, and their Value in the Treament of Consumption;" and Dr. Rabagliati concludes his paper "On the Nature of so-called Specific Fevers." As a very natural sequel to this we have a paper on the Eagley outbreak and the propagation of enteric fever by infected milk, which proves to be another instance pointing to the necessity for regulation and adequate supervision over the sanitary circumstances of dairy farms.

The Monthly Microscopical Journal bears evidence of the activity with which microscopical research is carried on. Mr. Bevan Lewis, pathological assistant and medical officer of the West Riding Asylum, contributes an instructive paper on a method of preparing and staining fresh brain for examination. Mr. W. G. Farlow, Assistant Professor of Botany in Harvard University, U.S.A., contributes an interesting paper on a fungus disease which has appeared among the olive and orange trees of South California this year, and caused considerable loss to the growers. Dr. Woodward, of the Army Medical Department, U.S.A., has an important communication on the application of photography to the measurement of the blood corpuscles. Microscopy appears to be actively cultivated in America, and we notice that many of our medical contemporaries devote a considerable space to this department of science. The *Cincinnati Medical News*, among others, contains articles of interest to microscopists.

Science Gossip maintains its name and position as a medium of interchange of thought and gossip among students of natural history subjects.

Nature treats its readers to a double number this week, and it contains an abundant supply of food for the mind in a verbatim report of the British Association meetings. We would also direct attention to the admirable portrait and biographical sketch of Sir William Thomson, with which the number opens. Mr. Jeen's portraits on steel, which occasionally appear in *Nature*, are simply perfection.

Correspondence.

CASE OF TRIPLETS, WITH A FOURTH BLIGHTED FŒTUS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The following case has occurred in my practice during the past week, and as it may be interesting to the profession, or some compiler of obstetric memoranda, perhaps you will kindly allow it to appear in your journal:—

About 9 a.m. on the morning of August 25th I was summoned to attend the wife of a coal-miner in the village of Brownhills. About an hour and a-half after my arrival at the house she was delivered of a full-grown male child, the presentation of which was "breech." Some twenty minutes or more after its expulsion I made an examination, and found, on running my finger along the cord, a large, rounded, tense mass, which proved to be the membranes of another fœtus. I waited for some time to see if the uterus would resume its action. After the expiration of two hours I decided on rupturing the membranes, and in twenty-five minutes afterwards a second male child, considerably smaller than the first, was born: the presentation was "pedal." Upon placing my hand on the abdomen, after this second birth, I found the uterus nearly as large as at first, and very little reduced in size. I made another examination, and found the membranes of a third fœtus presenting; these I speedily ruptured, and another fully developed male child (the largest of the three) was immediately born; this presentation was also "breech." In about ten minutes after the expulsion of the third child the patient had a strong labour pain, and a fœtus of presumably about three or four months was expelled. There were two placentæ, and on examining them I found that the cords of the second and third child, as well as that of the blighted fœtus, were attached to one placenta, and that of the first child to the other placenta. The mother (who is about 32 years of age, and who, strange to say, has *twice been delivered of twins*) and the three infant male children are doing well.

I am, Sir, your obedient servant,

DAVID EDGAR FLINN, L.K.Q.C.P.I., L.R.C.S.I.

Brownhills, Staffordshire.

"ON THE FUNCTIONAL DISEASES OF THE URINARY ORGANS." BY DR. CAMPBELL BLACK.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—With what is simply a question of opinion regarding the merits or demerits of my book, reviewed in your last impression, I am not concerned, and consequently never interfere, but when I have to complain of wanton misrepresentation, I hope you will allow that I am entitled to be heard, and that correction is due to me.

Firstly, your reviewer disingenuously insinuates that I participate in opinions *which I have distinctly controverted in my book*. For example, in the reference to "phthisis and clergyman's throat."

Secondly, the following paragraph foists upon me statements which I cannot reprobate too strongly. "Finally, fornication is used as a remedy. Lallemand, B. Phillips, Mr. Erichsen, the Greek Church, Cicero, Dugald Stewart, and Strauss all appear to be summoned as authorities in recommending this more than questionable piece of advice." It is not the least creditable to your reviewer that he should use his position in thus doing what is nothing short of maligning me, and I refer any one sufficiently interested in the matter to my book in order to satisfy himself that this is the case. What I have maintained, and what I still maintain, in common with so many others, is that the normal excercise of all the functions of the body must be conducive to the health of the organs themselves and the system generally, and I cannot, by any logical or reasonable possibility, escape from this conclusion in the case of the generative organs. *In what manner, or under what contract, this end is to be accomplished is a question on which I have never presumed to dictate*, and I must therefore repudiate the libel that I have ever given countenance to, or recommended fornication in the manner so flagrantly misstated by your reviewer.

I am, &c.

D. CAMPBELL BLACK.

Glasgow, September 7, 1876.

[As the reviewer of Dr. Campbell Black's book is travelling, and will not have the opportunity of seeing the objections raised until his return in October, we insert the letter in fairness to Dr. Black, without, however, prejudicing the case, or anticipating the reply which our reviewer will doubtless feel it incumbent upon him to make.—ED. M. P. & C.]

MEDICAL PRACTICE IN SOUTH LONDON.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I perceive that Mr. Lewis, as was but natural, has been mightily exercised by the letter I wrote to you concerning him a couple of weeks since, and attributes my so writing to "spite"—quite a mistake. It is a matter of indifference to me whether he sees his patients for infinitesimal fees or no fees at all; what I object to is his touting for patients by means of handbills—some of which have been left by his agents at my own door!—and a large black-board with his qualifications, hours of attendance, and terms painted on it, and placed outside his door. I am content to leave the matter in the hands of the profession, and in yours, Sir,

And remain, &c., &c.,

NEMO.

◆

MR. FAVELL'S "ADDRESS IN SURGERY."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As I am the individual referred to by W. F. Favell, Esq., under the initials A. B., in his "Address in Surgery," delivered before the British Medical Association, and published in your issue August 23rd, perhaps you will allow me to correct, as briefly as possible, a few errors as to facts into which he has fallen.

I never had a splint of any kind applied. Within three days certainly, if not before, I complained to Mr. B., the surgeon attending me, of shortening (I said, "I cannot get my knees together") and inversion, and continued to complain every time he came; and it was because of my complaints—not for his own satisfaction—that the third surgeon was called in five weeks after the accident. Instead of agreeing with the treatment he changed it completely. He found me kept at rest on my back painting the hip with iodine. He ordered me to discontinue the iodine, to use "Lin. Tereb. Acet. R.P. ter in die." with strong friction; to get up immediately and begin to walk; and enjoined me not to be afraid of using or hurting my leg.

These orders I faithfully obeyed, under the personal supervision of Mr. B., who continued to attend me seven weeks longer. I must add that Mr. B. from the first described my injury as "partial dislocation of the hip, with severe bruises," and wrote those very words on my application to the Railway Passengers Accident Association Company. I believe that paper is still in existence at their office. All through his attendance Mr. B. adhered to it that my hip had been out of joint, and he had put it in.

Yours, &c.,

A. BALMFORTH.

5 Pershouse Terrace, Ardwick, Manchester,
September 9th, 1876.

SUDDEN DEATH OF DR. SIBSON, F.R.S.

THE profession will be pained and shocked by the sudden death of Dr. Sibson, which took place suddenly on Friday, while deceased was on his holiday tour in Switzerland. The telegram conveying the sad news does not mention the cause of death, but every member of the profession who had the pleasure of Dr. Sibson's acquaintance will, on hearing the announcement, mourn the loss of a most amiable friend, as well as a most accomplished physician. The deceased held the degrees of M.D. London and Dublin, F.R.C.P., D.C.L., F.R.S., was a Vice-President of the Royal Society and of the British Medical Association, and Consulting-Physician to St. Mary's Hospital. Medical literature has been much enriched by his pen, particularly by his contributions on the subject of Respiration, and his Gulstonion and Croonian Lectures.

THE NEW HOTEL DIEU.

THE new hospital—a vast establishment situated in the place Notre Dame, at Paris, directly opposite the time-honored old institution, and built on the pavilion principle, is being pushed forward to completion with the greatest activity. The building of the old hospital will be finally removed before the exhibition of 1878, and the square which will adorn the façade of Notre Dame will be quite complete before that time. At the present time, the fountains which are to decorate the gardens in front of the new hospital are in course of construction.

THE MEDICAL CONGRESS AT TURIN.

A MEDICAL congress will be held from the 18th to the 28th of September at Turin. It will be divided into several sections, and there will be at the same time an exhibition of different objects relative to medicine produced exclusively in Italy within the last few years.

THE collection of the Jardin d'Acclimation in the Bois de Boulogne have received very interesting accessions recently. Two of the eatables (!)—dogs of China, which are, it seems, the tit-bit of the *gourmèts* of the celestial empire—have been sent by the French consul at Canton, as well as several of the Chinese telescope fish. This addition to the animal kingdom is purely a Chinese invention. The servants of that nation have succeeded, by the help of means unknown to us, in breeding from the golden carp the strange monster which they have called the telescope fish, from the prodigious development of its head and eyes, which project from the orbits like the stern eyes of lobsters, and are supposed to possess extreme far sight.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the MEDICAL PRESS AND CIRCULAR, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat, after it has passed through the post.

SUBSCRIBERS who have not yet sent in their subscriptions for last year are respectfully reminded of the omission.

LAW RESPECTING PERIODICALS, NEWSPAPERS, &c.—1. Subscricers who do not give express notice to the contrary, are considered as wishing to continue their subscriptions. 2. If subscribers order the discontinuance of their periodicals or newspapers, the publisher or publishers may continue to send them until all arrears are paid up, and Subscribers are held responsible for all numbers sent. 3. If Subscribers neglect or refuse to take the periodicals or newspapers from the office to which they are directed, they are held responsible till they have settled their bills. Sending numbers back, or leaving them in the office, is not such notice of discontinuance as the law requires. 4. If Subscribers remove to other places without informing the publisher, and their periodicals or newspapers are sent to the former directions, hey are held responsible.

MR. GEORGE STOKER, L.R.C.S.I., having volunteered for surgical services during the period of the war, has been appointed by the Turkish Ambassador, and left London on August 27th *en route* for Constantinople, from whence he proceeds to the seat of war.

APPOINTMENTS.

SPENCER, JOHN A., L.K. & Q.C.P.I., L.M., L.R.C.S.I., Medical Officer for the Ahascragh District of the Ballinasloe Union, and for the Clonbrock District of the Mountbellew Union, both in the co. Galway, vice Thomas G. Kerans, L.K. & Q.C.P.I., &c., resigned.

THOMPSON, J., A.B., M.B., L.K.Q.C.P.I., L.R.C.S.I., Surgeon to the Borough Police, Royal Leamington Spa.

TURNBULL, A. R., M.B., C.M., Junior Assistant Medical Officer to the Royal Lunatic Asylum, Morningside, Edinburgh.

SPARKS, G. W., M.R.C.S.E., Medical Officer and Public Vaccinator for No. 2 District of the Mansfield Union, Notts.

◆

Marriage.

MATTHEWS—FLINDERS.—On the 5th inst., at Aberdovey, Merionethshire, John Matthews, M.D., of 30 Colebrooke Row, Islington, N., to Mary, second daughter of the late Samuel Ward Flinders, Lieut. R.N.

◆

Deaths.

FRY.—On August 30, at Boyle, John Baker Fry, M.D., for many years Assistant-Surgeon of the Roscommon Militia, aged 36.

HANSON.—On September 1, at Brentwood, Essex, Newton Hanson, M.R.C.S.E., aged 76.

ROGERS.—On September 6, at Hillview, Delganey, Emily Frances, the beloved wife of John W. Rogers, M.D.

SCRAGGS.—On September 1, at Clogher, co. Tyrone, Matthew R. Scruggs, M.D., M.R.C.S.E., aged 64.

SIBTHORP.—On September 6, at 18 Hume Street, Dublin, suddenly, Henry James Sibthorp, M.D., L.K.Q.C.P., &c., aged 71.

YOUNG.—On September 4, at Hastings, Adam Young, L.R.C.P. Edin., L.R.C.S. Edin., J.P. of Boston, Lincolnshire, aged 80.

GENERAL NURSING INSTITUTE for TRAINED HOSPITAL NURSES.

5 Henrietta Street, Covent Garden, W.C.

A. EBSWORTH, F.R.C.S., Director.

OBSTETRICAL SOCIETY OF LONDON.—The QUARTERLY EXAMINATION for MIDWIVES will be held on WEDNESDAY, OCTOBER 11th. Candidates should apply at the Society's Library, 291 Regent Street, W., on or before September 30th.

SOCIAL SCIENCE CONGRESS, LIVERPOOL, OCTOBER 11th to 18th.—President, the Most Hon. the Marquis of Huntley. Presidents of Department:—I. Jurisprudence—Farrer Herschell, Q.C., M.P. II. Education—Rev. Mark Pattison, B.D. III. Health—Thomas Hawksley, Esq., C.E. In this Department will be discussed the subjects of Water-Supply, Registration of Disease, and Noxious Vapours and Smoke. IV Economy and Trade—G. J. Shaw Lefevre, Esq. M.P. V. Art—E. J. Poynter, Esq., R.A. President of Council, G. W. Hastings, Esq. Chairman of Repression of Crime Section, T. B. L. Baker, Esq. Papers to be sent in by September 30th. Full particulars may be had at the offices of the Congress, 1 Adam Street, Adelphi, London, or Town Hall, Liverpool.

C. W. RYALLS, General Secretary.

ST. BARTHOLOMEW'S HOSPITAL and COLLEGE.—The WINTER SESSION will begin on MONDAY, OCTOBER 2nd. The Clinical Practice of the Hospital comprises a service of 710 beds, inclusive of 34 beds for Convalescents at Highgate.

Students can reside within the Hospital walls, subject to the College Regulations.

For all particulars concerning either the Hospital or College, applications may be made, personally or by letter, to the Resident Warden of the College.

A handbook will be forwarded on application.

THE LONDON HOSPITAL and MEDICAL COLLEGE.

HOSPITAL STAFF.

Consulting Physician—Dr. Herbert Davies.
Consulting Surgeons—Mr. Luke, F.R.S., Mr. Adams, Mr. Curling, F.R.S.
Physicians—Dr. Andrew Clark, Dr. Ramskill, Dr. Langdon Down, Dr. Hughlings Jackson, Dr. H. G. Sutton, Dr. Fenwick.
Assistant Physicians—Dr. Woodman, Dr. Stephen Mackenzie, Dr. A. E. Sansom, Dr. Charlewood Turner.
Surgeons—Mr. Hutchinson, Mr. Maunder, Mr. Couper, Mr. Rivington, Mr. James Adams, Mr. W. Tay, Mr. M'Carthy.
Assistant Surgeon—Mr. Reeves.
Obstetric Physician—Dr. Palfrey.
Assistant Obstetric Physician—Dr. Herman.
Surgeon-Dentist—Mr. A. W. Barrett.

LECTURERS.

Medicine—Dr. Davies and Dr. Fenwick.
Surgery—Mr. Couper.
Operative Surgery—Mr. Maunder.
Anatomy—Mr. Rivington.
Practical Anatomy—Dr. Wilson.
Physiology and Practical Histology—Mr. M'Carthy.
Chemistry—Dr. C. M. Tidy.
Comparative Anatomy—Dr. Ed. B. Aveling.
Midwifery—Dr. Palfrey.
Forensic Medicine—Mr. Rodgers and Dr. Tidy.
Materia Medica—Dr. Prosser James.
Botany—Mr. Baker.
Pathology—Dr. Sutton.
Diseases of Throat—Dr. Morell-Mackenzie.
Anatomy and Pathology of the Teeth—Mr. Barrett.

The next WINTER SESSION will commence on MONDAY, OCTOBER 2nd, 1876, when the Introductory Lecture will be given by Dr. Andrew Clark, Senior Physician to the Hospital.

The perpetual fee to Lectures and Hospital Practice, with two years' Practical Anatomy, is 90 guineas if paid in one sum, or 100 guineas if paid by three instalments. Special entries can be made to Lectures or Practice.

The Hospital contains about 800 beds. The In-patients during 1875 were 5,804, and the Out-patients, 40,717.

1, 2- Two Entrance Science Scholarships, value £60 and £40;
3, 4. and two Buxton Scholarships, value £30 and £20, will be offered for competition at the end of September. Entries for the above must be made on or before the 20th September.
5. A Scholarship, value £20, in Human Anatomy, for first-year's Students.
6. A Scholarship, value £25, in Anatomy, Physiology, and Chemistry, for first and second year's Students.
7. A Hospital Scholarship, value £20, for Clinical Medicine.
8. A Hospital Scholarship, value £20, for Clinical Surgery.
9. A Hospital Scholarship, value £20, for Clinical Obstetrics.

A Prize of £5 to the Student who has attended most Midwifery Cases during the preceding twelve months. The Duckworth Nelson Prize, value £10, for Practical Medicine and Surgery (Biennial). Money Prizes to the value of £60 given annually by the House Committee, for zeal in Dressing Out-patients and knowledge of Minor Surgery.

For particulars as to Appointments see the Prospectus, which will be forwarded on application to the Secretary, Turner Street, Mile End, E.

Greatly increased facilities are now afforded by adjacent railways and tramways for rapid transit from the neighbourhood of the Hospital to other parts of London. The East London Railway Company's station is directly opposite the Hospital. Lodgings can be obtained in healthy localities in the immediate vicinity of the Hospital, at a very reasonable

---

ST. THOMAS'S HOSPITAL, ALBERT EMBANKMENT, WESTMINSTER BRIDGE, S.E.—The MEDICAL SESSION for 1876 and 1877, will commence on MONDAY, the 2nd OCTOBER, 1876, on which occasion an Address will be delivered by Mr. Francis Mason, at Four o'clock.

Gentlemen are informed that the Admission Fees to Practice and to all the Lectures may be paid in one of two ways:—

1st. One Hundred Guineas, paid on entrance, entitle a Student to unlimited attendance.

2nd. Payment by three instalments, namely, of £40, at the beginning of the first year, £40 at the beginning of the second year, and £30 at the beginning of the third year, entitles a Student after payment of the third instalment to unlimited attendance.

Special Entries may be made to any Course of Lectures or to the Hospital Practice; and a modified Scale of Fees is arranged for Students entering in their Second, Third, or any subsequent year.

Private Classes for Students preparing for Matriculation, and for the Preliminary Scientific Examination, and M.B. Examinations, of the University of London, or for other Examinations, are conducted by members of the Staff, and embrace instruction in Chemistry, Natural Philosophy, Botany, and Comparative Anatomy, Physiology, Anatomy, and Materia Medica. Gentlemen can attend these Classes without becoming Students of the Hospital.

PRIZES AND APPOINTMENTS FOR THE SESSION.

First Year's Prizes. Winter.—Entrance Scholarships of £60 and £40 awarded after an Examination in Physics, Chemistry, Botany, and Zoology. The Wm. Tite Scholarship of £30. College Prizes—£20 and £10. Summer Prizes—£15, £10, and £5.

Second Year's Prizes. Winter.—The College Scholarship of 40 guineas, tenable for two years. College Prizes—£20 and £10. Summer Prizes—£15, £10, and £5. The Assistant Dresserships, Clinical and Obstetric Clerkships are open to Students who have passed the Primary Examinations at the Royal College of Surgeons.

Third Year's Prizes. Winter.—£20, £15, and £10. In-Patient Clinical Clerkships and Dresserships.

The Cheselden Medal is awarded after a Special Examination in Surgical Anatomy and Surgery. The Mead Medal, awarded after a Special Examination in Practical Medicine and Hygiene. The Solly Medal, with a Prize of at least 10 Guineas, for a collection of Surgical Reports. The Treasurer's Gold Medal, for General Proficiency during the entire course of Study. The Grainger Testimonial Prize, for Physiological Essay illustrated by preparations. The Two House Physicianships. The Two House Surgeoncies. The Resident Accoucheurships.

A Medical and a Surgical Registrarship, at a honorarium of £40 each, is awarded to Third or Fourth Year's Students.

MEDICAL OFFICERS.

Honorary Consulting Physicians—Dr. Barker and Dr. J. Risdon Bennett.

Honorary Consulting Surgeon—Mr. Frederick Le Gros Clark.

Physicians—Dr. Peacock, Dr. Bristowe, Dr. Murchison, Dr. Stone.

Obstetric Physician—Dr. Gervis.

Surgeons—Mr. Simon, Mr. Sydney Jones, Mr. Croft, Mr. MacCormac.

Ophthalmic Surgeon—Mr. Liebreich.

Assistant Physicians—Dr. Ord, Dr. J. Harley, Dr. Payne.

Assistant Obstetric Physician—Dr. Cory.

Assistant Surgeons—Mr. F. Mason, Mr. W. W. Wagstaffe, Mr. A. O. MacKellar.

Dental Surgeon—Mr. J. W. Elliott.

Assistant Dental Surgeon—Mr. W. G. Ranger.

Resident Assistant Physician—Dr. Sharkey.

Resident Assistant Surgeon—Mr. Clutton.

Apothecary—Mr. S. Plowman.

LECTURERS.

Medicine—Dr. Bristowe and Dr. Murchison.
Surgery—Mr. Sydney Jones and Mr. MacCormac.
General Pathology—Dr. Payne.
Physiology and Practical Physiology—Dr. Ord and Dr. John Harley.
Demonstration in Physiology—Dr. T. Cranstoun Charles.
Descriptive Anatomy—Mr. Francis Mason and Mr. W. W. Wagstaffe
Anatomical Demonstrations in the Dissecting Room—The Anatomical Lecturers, Dr. R. W. Reid and Assistants.
Special Anatomical and Microscopical Demonstrations—Mr. Rainey.
Practical and Manipulative Surgery—Mr. Croft and Mr. MacKellar.
Chemistry and Practical Chemistry—Dr. A. J. Bernays.
Midwifery—Dr. Gervis.
Physics and Natural Philosophy—Dr. Stone.
Materia Medica—Dr. Payne.
Forensic Medicine—Dr. Stone.
Comparative Anatomy—Mr. C. Stewart
Ophthalmic Surgery—Mr. Liebreich.
Botany—Mr. A. W. Bennett.
Dental Surgery—Mr. J. W. Elliott and Mr. W. G. Ranger.
Demonstrations of Morbid Anatomy—Dr. Greenfield.
Lectures on Morbid Anatomy and Practical Pathology—Dr. Greenfield.
Mental Diseases—Dr. Wm. Rhys Williams.
State Medicine—Dr. Alfred Carpenter.

W. M. ORD, M.B., Dean.
R. G. WHITFIELD, Medical Secretary.

Any further information required will be afforded by Mr. Whitfield.

IRISH POOR-LAW INTELLIGENCE.

THE EXAMINATION OF DANGEROUS LUNATICS IN IRELAND.

The working of the recent enactment for the examination of dangerous lunatics by the Poor-law Medical Officers, and the payment of a fee to the latter for their services, has proved on the whole satisfactory inasmuch as a ready means has always been available to those who desired the necessary medical certificate, and at the same time the justice of the medical officer's claim for payment has been generally admitted. It was not, however, to be expected, that an additional charge upon the rates, however small, could be imposed without some grumbling on behalf of the ratepayers, and several instances have occurred in which the fee to the medical officer has been disputed by the guardians, who seem to consider that this duty should be performed by the dispensary doctor as a part of those multifarious functions purchased by his noble salary.

As to the legality of the payment of fees for lunatic certificates, there need be no dispute, for the Irish Medical Association has settled the question by an appeal to the opinion of eminent Counsel, and the Local Government Board has ordered the payment in more than one case in which the guardians hesitated. As to the fairness of the demand we would appeal to the sense of justice of those who object, and we ask them to reconsider their objection. Surely, though they call upon the Dispensary Doctor, in return for a salary paid him for a particular service, to perform another and totally different duty, they would not think of applying such a rule to their own domestic life. If they pay wages to a cook to serve their dinners, will they think of asking her to drynurse the baby on its arrival in the household, because, in their opinion, she is overpaid for her cookery? Or would they grumble if their groom asked for more wages for cultivating the garden without having been engaged to do so. We venture to point out to these gentlemen that dispensary doctors were not engaged to certify dangerous lunatics, that duty having been imposed in the most audacious way by Lord O'Hagan, by the Dangerous Lunatics Act of 1867, in spite of the vehement protest of the profession. A dispensary doctor is paid his Poor-law salary for well-defined duties, which have to do with the treatment of disease, and with nothing else, and the Legislature and successive governments have always recognised that any functions added to these are extraneous, and to be paid for by additional salary. Vaccination and sanitation are much more nearly akin to doctoring than lunacy certifying, and yet they are very properly recognised as extra work, and paid for as such, and the most parsimonious of ratepayers would hardly suggest that they ought to go into the dispensary salary. Another strange view held by some persons is that this duty and others of the same class might be paid for if they entailed a long journey, but ought not to be recognised if they did not require driving or walking in their performance. It seems to be forgotten by such logicians that the public do not pay doctors for the use of their legs, but for the use of their brains, and that a dispensary officer receives his salary principally for the knowledge which he possesses of disease, and only in a small degree for carrying his knowledge across the country. A village attorney, who grumbles at paying a doctor's fee because the patient is brought to his door, would be the last person to measure his own services by the number of miles got over, or the number of minutes spent, and it will hardly be suggested that a certificate given at home is of less value than one given elsewhere.

It is surprising that any country gentleman should forget what is fair in his anxiety for what is cheap, and we hope that there will be found few Irish guardians who will object to a fee for lunacy certificate, if he fairly considers the arguments which we have put forward.

Appropriately to this subject we record a case which has lately come under our notice. A Poor-law Medical Officer, X, was called upon by the relatives of a patient to examine and certify the patient as a lunatic, which he did. The relatives presented this certificate to a local magistrate, who happened to be a governor of a lunatic asylum, and who straightway gave him an order for admission therein. The medical officer applied to the magistrate to certify for his examination fee under the 14th Section of the 38th and 39th Vict., cap. 67, which the latter declined to do, because, as he said, he had sent the man to the asylum, not in his capacity as a magistrate, but simply as a governor.

This objection, though *primâ facie* a matter of hair splitting, appears to us to be quite legal. The 10th section of the 30th and 31st Vict., cap. 118, provides that "Whenever any person shall be brought before two justices, and it shall be proved to their satisfaction that such person was discovered and apprehended under circumstances denoting a derangement of mind, and a purpose of committing some crime for which, if committed, such person would be liable to be indicted, the said justices shall call to their assistance . . . the nearest available medical officer of the dispensary district in which they shall be at the time, who shall examine such person without fee or reward; and if such medical officer shall certify that such person is a dangerous lunatic, it shall be lawful for the said justices to direct that such person shall be taken to the lunatic asylum."

This clause is amended by the 14th section of the Act of last year, which provides that, "notwithstanding anything in 30 & 31 Vic., cap. 118, sec. 10, it shall be lawful for any two justices causing any person to be examined by any medical officer as therein mentioned, if they think fit so to do, to make an order under their hands and seals upon the guardians of the union to which such person belongs, for the reasonable remuneration to such medical officer and for the payment of all other reasonable expenses in or about the examination of such person, not exceeding in the whole the sum of two pounds.'

It will be obvious that the authority of the magistrate to order payment of the medical officer applies to the discharge of duties "therein mentioned," *i.e.*, in the section previously quoted, and inasmuch as this latter proviso applies specially and only to the case of a lunatic "discovered and apprehended under circumstances denoting . . . . a purpose of committing some (indictable) crime," it seems evident that a medical man must—in the case of a patient brought up by his relatives without the intervention of the police, look to the relatives for his fee.

CORRESPONDENCE.

FEES TO MEDICAL WITNESSES.

TO THE EDITOR.

SIR,—Your correspondent, "Only a Dispensary Doctor," *can avoid* the ill-paid and unpleasant duty of giving evidence under the Vaccination Act without a proper fee, if (as his letter infers) the Petty Sessions Court is *outside* his district, by adopting the plan followed by me when placed in a similar way, viz. : There was no Petty Sessions Court in my district, and the district was so situated that it formed parts of three Petty Sessions districts. When called on to appear as a witness under the Vaccination Registration Acts, I declined to do so unless a fee of £2 2s. 0d. was secured to me, on the grounds that I was appointed medical officer for the *dispensary districts*, and that any duty *inside* that district I was ready to perform, but that nothing in the regulations made it my duty to go a stop outside that district without proper remuneration. I need not say that the fee was *not* forthcoming, consequently, having got no *order* from *head*-quarters, I did not go during the time I held office.

Yours faithfully,

AN EX-DISPENSARY DOCTOR.

BOYLE UNION.

DR. KISBY'S SALARY.

The following letter was read :—

"Local Government Board, Dublin,
"4th August, 1876.

"SIR,—The Local Government Board for Ireland acknowledge the receipt of minutes of proceedings of the Board of Guardians of the Boyle Union on the 25th ultimo, containing a resolution proposing to reduce the salary of the medical officer of the Ballyfarnon Dispensary District from £120 to £100 a year, and in reference thereto the Local Government Board request that the guardians will be so good as to inform them of the grounds on which it is proposed that the salary of the medical officer should be reduced.

"By order of the Board,
"B. BANKS, Secretary.

"To the Clerk, Boyle Union."

Mr. MacDermot—The majority of the Board acted on the recommendation of the Dispensary Committee, who were aware of the amount of work done.

Mr. Mulhall—This is a very serious charge against a man, when there is no specific charge made against him. It is not fair to treat a man badly without discussing it.

Mr. Johnston—It is not the wish of any member of the Ballyfarnon Dispensary Committee to treat him as you say.

Mr. MacDermot—I understand that Dr. Kisby refused to attend a meeting of the Dispensary Committee, although he was asked to do so.

Mr. Johnston—He did.

Mr. Mulhall—What charge did the Dispensary Committee make against Dr. Kisby that his salary should be reduced?

The minutes of a former Board were referred to, containing a report of proceedings of the Ballyfarnon Dispensary Committee, at which it was proposed to reduce Dr. Kisby's salary from £120 to £100 per annum, and when read by the acting clerk,

Mr. Martin said there was no reason given in it for the reduction of Dr. Kisber's salary.

Mr. Mulhall—There is no reason given there, and there ought to be a charge brought against a man before you reduce his salary.

Mr. MacDermot—I think the reason was that it was considered £100 was sufficient for the amount of work done.

Mr. Mulhall—But there is as much work to be done now as there was for the £120. Is that fair?

Chairman—I think the answer to this letter is that the majority of the Board acted on the recommendation of the Dispensary Committee.

Several guardians concurred in this opinion, and an order was made to that effect.

KISBY *v.* BOYLE GUARDIANS.

Mr. Joseph Burke, solicitor, wrote to say that as the guardians considered it necessary the items of decree should be stated, he informed them they would now have to pay 5s. for the correspondence, so that the whole bill now amounted to £2 5s. 6d.

Dr. Drapes sent in a bill also.

Clerk—This is a case of the same kind. I sent him a copy of the Public Health Act, and told him he was the officer to attend.

Chairman—I left the case before the board and advised them to allow it, so that they might not be going into law again.

Clerk—If we went into law this time we would not get off so easy, because we got a caution before.

Chairman—The day the bill came up I asked the board to pay it.

Mr. J. Devine—Were the circumstances similar with the last case?

Clerk—The very same.

Mr. McKeon—He had no right to claim it, because he had only to walk across the road. Besides, it will become a general thing.

Mr. J. Devine—We never heard of such demand before till Dr. Kisby, and I think this matter should be fought out to the last.

Clerk—The second section of the Vaccination Act requires the medical officer to prosecute.

Mr. J. Devine—Well, this matter should be attended to.

DUNGARVAN GUARDIANS.

WORKHOUSE WHISKEY.

A REPORT of the medical officer, Dr. Hunt, as read by him, was as follows :—

"I found the strength of the whisky 37·6 under proof. My suspicions were aroused by not being able to attain the usual results in administering the whiskey. I for some time suspected that it must be the cause of weak whiskey. I determined to test it, and ordered a gallon of it to be sent down. On testing it that was the result. I think it also well to mention that it was at my suggestion a hydrometer was obtained, and it was taken possession of by the master, and very properly, as I believed it was more his duty than mine to test the quality of the whiskey sent into the workhouse. But when I required to test the whiskey, I could not do so until this hydrometer was obtained from the contractor—the very man that supplied the whiskey—so that instead of it being of use to the union, it was of more use to the contractor."

Capt. Fitzgerald—Why should it be in the hands of the contractor at all ?

Medical Officer—I cannot tell. The whiskey was 37 degrees under proof, and the money value of that is only 9s. 3½d. per gallon, and you pay 18s. 1d. for it. The hydrometer was purchased four or five years ago by the master.

Medical Officer—It makes a difference of 2d. in the value of the whiskey for every degree less than that specified.

Chairman—It is nearly 58 degrees less than it ought to be.

Medical Officer—That is 11s. 6d. you are losing on every gallon.

Mr. Hackett—It is the patients are sufferers by that.

Chairman—There are more than the patients suffering—the ratepayers also suffer.

A letter was here read from the contractor, stating that the junior apprentice had made a mistake in mixing the whiskey. The quantity ordered was small, else it would be prepared under his own supervision. Of late the supply of whiskey had been very much lessened, but at all times, except this time, the whiskey supplied by him was equal to sample. He hoped the board would consider this explanation, and begged to remain their obedient servant.

Medical Officer—It is very extraordinary. I did not test this whiskey for three or four years, and the very time I did I found it to be 50 per cent. under the sample. There has been a great deal said at this board about the quantity of whiskey consumed by the medical officer, and I think the guardians ought to supply me with whiskey and not grog. Then you come in and stand up and say It was a mistake of the contractor. You are losing 12s. 6d. a gallon on every gallon supplied.

Mr. Anthony—I would not take that view of the matter. You have administered that whiskey to the patients for three years, and you have never laid a complaint before the board up to this moment. You cannot charge the board with want of attention to it. (Chair).

Doctor—You are paying at the rate of 36s. per gallon for yous whisky.

Chairman—If the 20 per cent. overproof was over-ruled it ought to be on the minutes. It won't do to say it was over-ruled, because the proceedings of the board are on record, and the clerk says it was not over-ruled, The hand-bill does not mention any age, only 20 degrees over proof.

Mr. Anthony said that country people require whiskey for 12s. a gallon.

Mr. Terry—12s. per gallon !

Mr. Anthony—Yes, and I sell it myself.

Several Voices—Poison ! poison !

Mr. Anthony—Instead of being poison it is quite the reverse, because you might drink it with the greatest possible safety.

Mr. J. Terry—It is poison.

Mr. Anthony—Most emphatically, no ! I say the doctor has gone too far with this discussion. There are men in the trade as good as any in your profession, and you were quite too hasty in your expressions in reference to them.

Medical Officer—I made use of no expressions that could be objectionable to any man. (Noise.)

Capt. Fitzgerald moved, and Mr. Hackett seconded, that the Local Government Board be asked to have a sworn inquiry into the matter.

Mr. Terry asked Capt. Fitzgerald as a favour to withdraw his motion.

Capt. Fitzgerald said he would not do so if the contractor refunded to the guardians the difference between 9s. 3½d. and 18s. 1d. for every gallon of whiskey he supplied since the date of his contract.

Capt. Fitzgerald—Every day I come here I see the necessity of having paid guardians.

Chairman—I have heard this report myself with a great deal of pain, because I happen to know the contractor a long time, and always looked upon him as a respectable man, but at a public board like this we must do our duty. He would ask how could an investigation be of use to them.

Mr. Anthony—It will end in nothing. I think the only way to deal with it is in the same manner as the other contractors.

Capt. Fitzgerald—There is a lot of jobbing here. (Noise.)

Mr. Anthony, amidst frequent interruptions from Capt. Fitzgerald, proposed, and Mr. J. M. Terry seconded, an amendment—"That the whiskey tested by the medical officer, and found inferior to that tendered for. be returned to the contractor, and that he be required to supply whiskey in accordance with the terms of the advertisement."

Capt. Fitzgerald—Every day I attend here I am more convinced of the necessity of having paid guardians. The speaker then left the room hurriedly, exclaiming, "If you are inclined to do what's wrong I can't stop you. Good evening, gentlemen ; good-bye, gentlemen.

The amendment was then put and declared carried. The discussion occupied the board over two hours.

REPORT OF HEALTH OF DUBLIN AND SUBURBS FOR WEEK ENDING SEPT. 2, 1876.

Total registered deaths in Dublin and suburbs *	148	
Ten years average of same week	142	
Excess of mortality above average	6	
Ratio of deaths, suburb of Rathmines	24·3	per 1,000
” ” ” Donnybrook †	14·0	”
” ” ” Blackrock	7·2	”
” ” ” Kingstown	30·9	”
” ” Entire Dublin district	24·5	”
COMPARATIVE RATIOS—London	18	”
” ” Glasgow	21	”
” ” Edinburgh	17	”

* District extends over 10,050 acres, and contains 314,669 persons.

† This district includes City of Dublin and Incurable Hospitals.

The deaths from zymotic diseases amounted to 42 (the average of ten years was 42·2). Of the deaths from zymotic diseases, 10 were referred to fever (9 typhoid and 1 simple continued fever), 6 to scarlet fever, 20 to diarrhœa (18 of them being children under 5 years of age), 3 to croup, &c.

Seventeen children died from convulsions.

Fourteen deaths resulted from bronchitis, 3 from pneumonia, 2 from asthma, and 1 from lung disease unspecified.

One death was caused by apoplexy, a like number by paralysis and epilepsy, 3 by cephalitis, and 4 by brain disease unspecified, 5 by heart disease, 4 by peritonitis and 1 each by inflammation of the stomach, inflammation of the bowels, hernia, stomach disease unspecified, liver disease, cystitis, and kidney disease unspecified.

Thirteen deaths were attributed to phthisis, 2 to mesenteric disease, 1 to hydrocephalus, 4 to dropsy, and 3 to cancer.

Two accidental deaths were registered during the week.

Thirty-two of the deaths registered occurred in hospitals and other public institutions; of this number 4 took place in the North Dublin, and 9 in the South Dublin Union Workhouse.

◆

CASTLEBLAYNEY UNION.

The following was read from Dr. Donaldson, of Newtownhamilton, and dated 8th August:—"Gentlemen,—I most respectfully beg to submit my application for the sum of £6, half the amount paid by me to Dr. M'Keogh, as *locum teuens*, for four weeks' attendance during my absence. You will see by the minutes of my dispensary committee of the 27th May last that my committee very kindly promised to bear half the expenses of my substitute during the four weeks for which they allowed me leave of absence. Trusting you will confirm the proposal of the committee in this matter and refund me half the salary agreed to,—I am, &c.,

"W. W. Anderson, M.D."

A copy of the minutes of the dispensary committee's meeting was received, and it appeared that a majority of the committee agreed to pay half the expenses of Dr. Anderson's *locum tenens* during his absence.

On inquiry, it appeared that Dr. Anderson waa not unwell when on leave, and that the paying of part of the expenses under these circumstances was illegal.

It was moved that the resolution of the committee agreeing to pay half the expenses in question be confirmed, and an amendment was moved that no allowance be granted in the case. On a division an equal number voted for the motion and the amendment, so that Dr. Donaldson will have to apply again.

◆

NEW ADULTERATION OF QUININE.

The *Alger Médical* (*L'Union Pharmaceutique*) contains a communication with reference to a new and clever adulteration of quinine. The salt is put up in bottles identical with those issued by Pelletier, Delondre et Levaillant, bearing the same label and red seal. On examination it is found very soluble in water, producing a distinct coldness on solution, and it is not quite so bitter as the pure salt. On chemical analysis it presented the reactions of quinine, but not very marked; and, in addition to a small quantity of quinine, there was found a salt of potash with an organic acid, probably salicylic.

THE PHYSIOLOGICAL NUMBER OF WHITE BLOOD GLOBULES.

M. **Grancher** communicated the results of his researches into the physiological number of the white globules in the adult to the Société de Biologie (*Le Mouvement Médical*). The results he obtained differ from what have usually been given up to the present time. Almost all physiologists say there is one white to every four or five hundred red globules; but M. Grancher finds that the proportion is much lower, one to every fifteen or eighteen hundred. He also found, contrary to what is generally accepted, that food does not augment the number of white globules, but that their number remains much the same during the entire day. The normal oscillations are much greater for white than red globules, so that the number of red globules in different healthy persons varies between five and six millions, and the number of white globules between three and nine thousand. M. Malassez's researches, which have been previously chronicled in The Doctor, led him to find a smaller proportion of white globules than what is usually accepted, but nevertheless greater than that found by M. Grancher.

CURIOUS INCOMPATIBILITY.

The *American Journal of Pharmacy* and the *St. Louis Clinical Record* contains a note by M. Melseus calling attention to the fact that, although potassium iodide and potassium chlorate are both entirely harmless in suitable doses, yet when administered together they combine in the stomach, producing potassium iodate, which is poisonous, as proved upon dogs. As a general rule, the chlorate is so unstable, and so ready to give up its oxygen, that it is not safe to combine it with any substance capable of oxidation.

The Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 20, 1876.

STUDENTS' NUMBER.

The changes in the medico-educational system, which will be found in our Students' Number of to-day, are almost altogether progressive improvements in the medical schools and hospitals, and only in a slight degree the result of any movement on the part of colleges or other licensing bodies. The medical teaching institutions of Great Britain and Ireland have been shouldering each other in a general move towards a more scientific and less rule-of-thumb education, and the competition between them for the patronage of the high-class student has given strength to that spirit of reform which the licensing bodies have, as a rule, done little to foster. We may predicate of 1876 what we said of the preceding year — that medical school education may be said to be emerging at the same time from the lethargic condition into which it had fallen, and the sciences cognate to medicine are receiving a degree of attention which they have long deserved but never previously received. This is particularly noticeable with respect to the more practical method now adopted of teaching these sciences, and especially those which, like physiology and histology, were formerly taught in such a manner that a theoretical knowledge of them was all that a student could take away from the schools. Nor can we fail to notice a like improvement in the medical and surgical education of the student, or fail to mark the difference between the qualifications with which the medical practitioner was formerly satisfied, and those which he is now anxious to take. The medical man who twenty years ago, thought himself fully qualified with one diploma, now takes two, with perhaps a good degree into the bargain; and he who formerly only knew how to use the stethoscope, and was satisfied with a very superficial knowledge of medicine and surgery, is now considered behind time if he is not *au fait* in the study of temperature, pulse tracings, antiseptic surgery, aspiration, germ, physiology, cerebro-spinal pathology, State medicine, and many other new lights of our profession.

The public will have learned, from our former efforts to inform students of their future career and its educational requirements, that we do not expect them to read legally-phrased official regulations, or to depend upon us for that sort of information. They will, no doubt, obtain it at first hand from the college school or hospital which they select, and we advise them to do so. These regulations will be usually found to be behind the time, and, in most instances, the study of advanced branches of medical study depends more upon voluntary ardour of students and teachers than upon the vigilance of licensing bodies. We conceive it to be our *rôle* to place in the hands of the Student and his guardians the semi-confidential details, directions, and hints which College Regulations are not intended to communicate, and which are only known to those conversant with the various systems of education, examination, and qualification, and with the ultimate prospects of the Student.

These details will, we hope, be found exhaustive and instructive, and such as to furnish our readers with the information most needful to them.

THE FIRST STEP IN MEDICINE.

REGISTRATION.

To the General Medical Council is entrusted the supervision of Medical Education, and it has made a number of recommendations, the majority of which have been accepted by all the Examining Bodies, and are, consequently, found in their regulations. The student has, therefore, nothing to do with the Council, except that he must take care to be duly registered as a Student in Medicine, *at the commencement of his career*, at the offices, 315 Oxford Street, London, in Dublin or in Edinburgh. He must in England previously have passed a preliminary *Arts Examination*. In order to effect this, each student should apply according to a form accompanied by a certificate of his having passed such examination, the same to be lodged with the Registrar, who will thereupon enter the name in the Students' Register, and issue a certificate to that effect.

The intention of this registration is to ensure that the student shall occupy four years in medical study, which is, theoretically, the period which must be devoted to his education before his entry to the profession. In England this requirement is set down as essential, and no student can present himself for examination sooner than four full years from the date of registration, but the obligation to occupy this period in medical study is frequently satisfied by a nominal service for the first year under a general practitioner, or in a provincial hospital or dispensary, and the actual period of medical study is often really three years.

The standard of medical education, however, as well as of the examinations of the various examining bodies, is so much higher than it formerly was, while our knowledge of medicine and the collateral sciences, and the scope of our medical studies, have recently become so enlarged, that four years is by no means too long a period to be devoted to medical study. And even the diligent student will find that at the expiration of this term he will have but an imperfect acquaintance with several branches of his profession.

In Ireland and Scotland the majority of the licensing bodies do not insist on the passing of Arts Examination before registration, nor do they insist on four years' study from any fixed date—a system which is reprehensible on the part of the licensing bodies, highly objectionable in its effect upon medical education, and very injurious to the student. It offers a premium to idle or uneducated students to put off the paltry preliminary examination *de die in diem* until the eve of his medical examination, and it enables the student to receive his diploma within less than three years of study, because the date from which his commencement is calculated is not fixed. Generally speaking, in Ireland the student's name is forwarded to the Registar of the Branch Council by the public officer of his school, and therefore he need give himself no trouble about it.

REGISTRATION OF PRACTITIONERS.

All duly-qualified Physicians, Surgeons, Medical Graduates, and Apothecaries are required by the Medical Act 21 and 22 Vic., c. 90, to be registered before they can hold any public medical or surgical appointment, or issue valid medical certificates.

The medical registration of any practitioner may be effected on personal application or in writing (according to a form to be had in London or at either of the Branch Offices). With such application he must produce or transmit the *Diplomas* to be registered, and also pay or remit the fee, which is regulated by the Medical Council—viz., £5 for first registration, and 5s. for every qualification which may be subsequently added. Each practitioner is entitled to receive a copy of the official Medical Register containing the registration free on application.

THE CAREER OF THE ENGLISH MEDICAL STUDENT.

SEVERAL courses are open to the young gentleman who has decided to enter the medical profession in England, whether he fulfil his curriculum in London or in the provinces. As the latter course is generally determined by local causes, we will first of all point out a few things that concern both London and provincial medical students.

APPRENTICESHIP.

The Society of Apothecaries, hitherto fettered by Act of Parliament, required an apprenticeship. The apprentice was, however, of late years allowed to fulfil part or all of his curriculum during his apprenticeship, and under the Act recently passed we presume the apprenticeship system will gradually die out. This system, be it said, when carried out in a liberal manner, was not without its advantages. In the early part of his pupilage the apprentice not only learned practical pharmacy, and became acquainted with the more generally used articles of the materia medica, but was often assisted in preparing for the preliminary examinations. He often, indeed, [illegible]d a thorough acquaintance with, and had indelibly impressed upon his memory, the doses of the different drugs used in medicine, the composition of the more important compound preparations, those drugs which are compatible and those which are incompatible with each other, and many other facts in practical pharmacy, of which, under the present system, even otherwise good men often show a lamentable amount of ignorance. Moreover, he prepared himself to take, should he ever wish to do so, the post of assistant to a general practitioner, as the experience he had thus acquired would procure him a situation in preference to prizes, gold medals, and even university distinctions. Again, this experience was of the very highest value on settling in general practice, especially in country practice, where he would, in all probability, be bound to dispense his own medicines.

PUPILSHIP.

Supposing that the plan of apprenticeship be rejected a young man can instead become the *pupil* of some one in practice. This is frequently done by those who aim at the higher branches of practice. An experienced practitioner, whether a physician or a surgeon, who will superintend or direct a pupil's studies, offers great advantages, and we think that those who can afford a pupilship, will not regret the expense of providing themselves with such a guide.

THE PRELIMINARY EXAMINATION.

We would remind the student that some preliminary examination in arts, which is recognised by the General Medical Council, *must* be passed by him *before* entering a hospital. The subjects must include Latin and mathematics. There are numerous preliminary examinations, of which a list may be obtained. For the English Medical Student we should say that *cæteris paribus*, the Matriculation Examination of the London University is the best. We do not deny that it is more severe than most of the other preliminary examinations, but, nevertheless, we would recommend those who have sufficient ability and the time to prepare for it to matriculate, as they will thereby be enabled hereafter, if they should desire so to do, to present themselves for examination for the degrees in Medicine or Surgery conferred by this University. It is also accepted by the College of Surgeons in lieu of the Arts Examination otherwise imposed on candidates for its Fellowship.

Should circumstances deter the student from offering himself for the matriculation, he will find an easier standard in one or other of the preliminary examinations for the Fellowship or Membership of the Royal College of Surgeons of England, or the License of the Society of Apothecaries. Full information with regard to the dates and subjects of examination, or the list of examinations recognised by these bodies, may be obtained from the Secretary to the College of Surgeons, Lincoln's Inn Fields, or from the Beadle at Apothecaries' Hall, Bridge Street, Blackfriars.

It is to be hoped, however, that the student has not gained a knowledge of classics merely with the view of passing the preliminary examination, or that these studies will not be entirely thrown aside and forgotten directly he has passed this examination. Independently of the mental discipline involved in the pursuit of these studies, the nomenclature adopted in the study of his professional subjects and the etymology of scientific terms, are so generally of Greek or Latin origin, that were it for this reason only it would be quite worth while for the student to keep up as far as possible a knowledge of these languages. At the same time the modern languages must not be forgotten; as a good knowledge of either French or German, especially the latter, will be found of great service to those who wish to enter the higher ranks of the profession, more particularly with respect to any future contributions they may make to medical literature.

As soon as the preliminary examination has been passed, or, at any rate, before commencing hospital study, it will be necessary for the student to register at the Medical Council, as the commencement of the course of professional study will not be recognised by any of the qualifying bodies as dating earlier than fifteen days before the time of registration.

HOSPITAL STUDY.

A pupil may enter at any of the London Hospitals without having passed through either a pupilship or an apprenticeship. Provided he nas passed a preliminary examination, he has only to pay his fees and hear the Introductory Lecture on the 1st of October, when he is admitted at once to all the privileges of a medical student. He should decide on the diplomas he requires, and guide his studies accordingly. Most schools have now a composition fee, entitling to all lectures and practice required for the ordinary qualifications in medicine and surgery. They also mostly have another sum, very little higher, entitling the student to *perpetual* attendance on all lectures and hospital practice. It is best to take the perpetual ticket, as all contingencies are thereby provided for. The fees are generally payable in instalments, at the commencement of each winter session. The Dean of any school will always forward details, as well as any special information which a student may need.

RESIDENCE.

The student who comes to London to fulfil his curriculum at a metropolitan school generally requires lodgings, unless he can live with relatives or friends, which is of course better. Comfortable furnished apartments are to be had in respectable streets near all the hospitals. Two brothers or two friends can, of course, do this a little less expensively than one. The price varies with the season and the quality of the rooms. It should be mentioned that one or two of the Medical Schools (St. Bartholomew's, University College, King's College) have collegiate institutions in connection with them, where rooms may be had instead of taking lodgings. At many schools, also, some of the lecturers receive pupils. Special information on this subject may be had on application to the Dean or any of the lecturers.

PRIZES AND SCHOLARSHIPS.

As to contending for prizes, there are differences of opinion. Diligent attendance on the classes and in the wards will enable the student to store his mind with knowledge fitting him for his profession, and this should be his first aim. Gold and silver medals are honourable distinctions, but only secondary ones. Still, we would not discourage those intending to compete. It should be remembered by all students that the true end and aim of their studies should be to make them good physicians or surgeons. They should study diligently to make themselves such, and there can be no reasonable objection to their striving for, in addition, an extra good standard in any subject or subjects in which they feel they are qualified to obtain it. In so far as prizes and scholarships encourage the study of particular branches, there can be no objection to them. Nearly every student excels in some subjects more than others, and a prize is an additional incentive to arduous but otherwise unrequited studies. The only danger is that they should become too special, and encourage one branch of study at the expense of the others. Students have often failed at examinations where the number of subjects was numerous through giving undue attention to some favourite branch of study.

Competition for appointments to dresserships and other offices, where much practice is seen, stands on a different footing. No prizes can equal such posts; and the possibility of getting them should influence largely the choice of a school. In some schools they must be paid for. In others the diligent gain them without extra expense. The student having selected his hospital and school, has chosen his teachers. We have only to remind him that, however able they may be, the result depends chiefly on his own application.

CURRICULA AND QUALIFICATIONS.

As to these, the information most valuable to students may be divided into two parts:—

I. The regulations with which they must comply before they can present themselves for examination to any of the licensing bodies.

II. The means that exist to enable them to do so. In the first division are to be placed the regulations of the corporations; in the second, some account of the many schools of medicine and hospitals where professional education can be pursued. A natural supplement to this information is a brief sketch of the career open to young men after they have obtained their diplomas, especially in the public services.

In accordance with this plan, we proceed to consider—first, the Regulations of the Qualifying Bodies. These may also be divided into two classes—I. The Universities; II. The Corporations.

THE UNIVERSITIES.

OXFORD AND CAMBRIDGE.

The older English Universities have lately opened their doors much wider than hitherto, without, however, losing any of their prestige. A valuable course of lectures upon every branch required by the medical graduate will be commenced next month in the University of Cambridge by some of the most able professors in the kingdom. Full information relative thereto may be obtained of Dr. Paget, Regius Professor of Physic. Those who propose to follow their course of education need not any longer enter at any particular college or hall, though it will be most probably long before lodger students became numerous There are advantages in a collegiate life that will not willingly be given up by those who can afford it. With respect to Cambridge (and almost the same remarks apply to Oxford) a residence during nine terms—*i.e.*, the greater part of each of three years, is by statute requisite to obtain any degree in arts, medicine, or any other subject. The actual cost of this to a student who keeps his terms by residence in a college is from £150 to £200 a year. This, however, would include all payments to the university and the college, all fees as well as clothes, pocket-money, travelling expenses, &c. But the non-collegiate students have only to pay the university fees, which are very small. They lodge and board as they like, and their expenses, therefore, are entirely in their own hands.

THE LONDON UNIVERSITY.

For those who would not like or cannot afford to enter a college, it is perhaps preferable to graduate at the University of London. The medical degrees of this university have now obtained a reputation second to none. No student can therefore propose to himself a higher qualification. The training is rather longer than is required for the diplomas of most corporations. The examinations are very stringent, but in after years the student will feel the gratification of having obtained such a degree. Every student is required to go through the full course of hospital studies *after* he has passed the matriculation examination. It is therefore very important that he should matriculate before entering a medical school, otherwise he will be compelled to stay more than four years at an hospital, as the University regulations require four years of hospital study and attendance on lectures *after matriculation*. The matriculation examination of this University is accepted as a preliminary by the Medical Council, and therefore the labour bestowed in preparation will serve the student's purpose even if he do not proceed to a degree.

We should also strongly recommend those students who intend to graduate at the London University to so arrange their studies as to pass the preliminary scientific examination *before commencing their regular medical studies*, taking a preliminary year for the purpose of preparation. In this way much knowledge will be gained which will go to clear the way for his first year's studies which would otherwise be mush encumbered. The medical degrees of the University are Bachelor and Doctor of Medicine, Bachelor and Master in Surgery, and Bachelor and Doctor of Science. There are at each stage of the graduate's career examinations for honours, which afford the student the opportunity of gaining highly-prized distinctions in various branches. There are prizes, exhibitions, and scholarships for the most successful.

Certain changes have recently been made in the regulations for the University of London's degrees of Bachelor and Doctor in Science. It has come to be generally felt that scientific knowledge, to be real, must be practical as well as theoretical, and that a thorough knowledge limited to a comparatively small range is preferable to a slighter acquaintance spread over a more extended area. In the first examination for Bachelor of Science, which every candidate will be required to pass, while the programmes in mathematics, experimental physics, and inorganic chemistry have been carefully revised, little fundamental change have been made in them. In place of the superficial acquaintance with both zoology and botany formerly required at this examination, there is a single examination (written and practical) in general biology, in which a more thorough knowledge is required of the simplest forms and elementary phenomena of animal and vegetable life. The regulations for the second B.Sc. examination, on the other hand, are framed with the view of allowing the candidate to bring up any three of the following nine subjects :—(1) Pure mathematics, (2) mixed mathematics, (3) experimental physics, (4) chemistry, (5) botany, including vegetable physiology, (6) zoology, (7) animal physiology, (8) physical geography and geology, (9) logic and psychology. Moreover, in the matricular examination, which forms the basis of the science curriculum, German may now be taken in substitution for Greek. In regard to the Doctor's degree, a change has been made in favour of candidates who prolong the interval between their first and second examinations for the degrees of Bachelor from one year to two or more, as such will be allowed to come up for the degree of Doctor of Science within a year of their attaining the degree of Bachelor.

UNIVERSITY OF DURHAM.

ences and three medical degrees are conferred by this University—viz., licence in Medicine and Surgery, and the degrees of Bachelor of Medicine, Master in Surgery, and Doctor of Medicine.

The candidate for a licence in Medicine must have been engaged in his professional subjects for four years after registration, and one of those four years must be spent at the University of Durham. The regulations for the licence in Surgery are similar to those for the licence in Medicine.

With regard to the degree of Bachelor of Medicine, no one will be admitted to that degree unless he has kept one year's residence in Arts at the Durham University College of Medicine, and has passed both the final examination for the degree of Bachelor of Arts, or an equivalent to it, and also the examination for the degree of Bachelor of Medicine.

No grace for the degree of *Doctor of Medicine* will be granted unless the petitioner is a Bachelor of Medicine of the standing of twenty-one terms (seven years) at least from his registration or matriculation, and of three terms at least from his admission to the degree of Bachelor of Medicine, nor unless he has written an essay based on original research or observation on some medical subject selected by himself, and approved of by the Professor of Medicine.

There is also an examination for the degre of Doctor of Medicine for medical practitioners of fifteen years' standing, *without residence*, and in which, unless he has previously passed an examination in Arts, he is examined in Classics and mathematics.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

The high position which this venerable College holds among the corporations is too generally acknowledged to require any particular attention being drawn to it. And it is gratifying to know that this College has lost none of its prestige by sympathising and becoming more associated with the general body of practitioners. Its licence is an honourable one, the examination for this licence very fair and up to a good standard, and we are surprised that students are ~~not more~~ ambitious than they are to enter the profession through its portals.

The Fellowship.—The Fellowship of this College is attainable only by election, and no one can be proposed who is not a member of at least four years' standing.

The Membership.—A person may become a member of this College without holding a degree in medicine, or, indeed, any diploma. But every candidate who shall have commenced his professional studies after September, 1861, shall satisfy the Censors' Board that previously to the commencement of his professional studies he has obtained a degree in Arts from some university of the United Kingdom or of the Colonies, or from some other university specially recognised by the Medical Council; or that he has passed examinations equivalent to those required for a degree in Arts. The curriculum extends over five years.

Graduates in Medicine of any British University are admitted to an examination for the Membership. Such graduates are exempt from some parts of the examination —*e.g.*, anatomy and physiology. Even graduates of accredited foreign universities have no difficulty in being admitted to examination. All persons who have been admitted before February 16, 1859, licentiates of the College, and also all extra-licentiates who are not engaged in the practice of pharmacy, may be proposed to be admitted a Member of the College. Every candidate for the membership is expected to pass an examination, but there are certain cases, referred to under sections 15, 16, and 17 of the by-laws of the College, in which the candidate is exempted from some portion of the examination.

The Licence.—The Licence of this College is a qualification to practise medicine, surgery, and midwifery, and is recognised by the Poor-law Board as a qualification in surgery as well as in medicine, but unless a graduate of some university, he is forbidden to use the title of doctor, but we regret to say many do so. It was regarded at first as a diploma for the general practitioner, intended to supersede that of the Apothecaries' Company. The examination is conducted by specially appointed examiners, and is complete in the several departments. There are two examinations for the Licence, the *first* of which may be passed after the termination of the second winter session; while the *second* examination cannot be passed until after four years of professional study. The fee for the College licence is fifteen guineas, of which five are to be paid on admission to the first examination.

Every candidate for the College Licence will be required to produce satisfactory evidence of having completed the course of study in accordance with the by-laws and regulations of the College, which may be obtained of the Registrar, and to pass the professional examinations conducted by the Examining Board.

Nearly eight years ago the most important change occurred that has ever taken place in reference to the qualifications of general practitioners. This Licence of the London College of Physicians was then recognised by the Poor-law Board as a qualification in surgery as well as medicine. Consequently, this single diploma is sufficient to enable anyone to take a Poor-law appointment. Anyone contented with the diploma of L.R.C.P. Lond. would thus have all he needed as a legal qualification.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

No College has exercised more influence over the profession than this. Without the M.R.C.S. it is not easy to obtain any English surgical appointment. Its membership, although no longer essential, yet carries great weight in a parish appointment. For this reason most English students take this diploma, which, together with a medical qualification, suffices for every purpose of the general practitioner. The College gives four diplomas, the Membership, Fellowship, a diploma in Dental Surgery, and one in Midwifery, which last is, however, mostly confined to those who are already members.

THE MEMBERSHIP.—This diploma gives no vote in the affairs of the College. It is only a licence to practise, and corresponds with the licentiateship of the Edinburgh and Dublin Colleges.

In future, candidates for the diploma will be examined in the Practice of *Medicine*, although there are certain conditions on which he can claim exemption. He must also have passed the preliminary examination of the College, or one that is recognised by the College. There are now two professional examinations for the Membership, the Primary and the Pass.

THE FELLOWSHIP.—Members of long standing are often admitted to the Fellowship by election. As, however, this grade is obtainable by examination, is of greater value, and needs no personal influence, men who have sufficient time and ability prefer the F.R.C.S. after exam.

For the Fellowship he must be a Member of the College of eight years' standing, and is admitted to examination on producing a certificate signed by three Fellows to the effect that he has been engaged in the Practice of Surgery for eight years, and is a fit and proper person to be admitted a Fellow.

Few consulting surgeons in England are without the Fellowship, and in most of the London hospitals appointments are unattainable without it.

APOTHECARIES' SOCIETY OF LONDON.

The Licence of the Society of Apothecaries is perhaps the most useful medical diploma for the general practitioner in England. The monopoly enjoyed by this body for many years, in this respect, is not easily to be disturbed. The laws of many institutions require their medical officers to hold this diploma, and these laws are not readily altered. Though other medical qualifications are recognised by the Poor-law Board, there is no doubt that the guardians throughout the country—and they elect the medical officers—are familiar with the diploma of the Apothecaries' Society, and it is to them more of a guarantee than other qualifications of which they are ignorant. Everyone, therefore, intending to settle in *England* as a general practitioner—even if he take other diplomas—would probably consult his own interest by taking up the L.S.A.; and as the fee is only six guineas, a very large number of young men will, no doubt, secure this avenue to appointments.

◆

NOTES ON THE
HOSPITALS AND MEDICAL SCHOOLS IN LONDON:
CHIEFLY IN REFERENCE TO THE PRIZES, SCHOLARSHIPS, AND APPOINTMENTS OPEN TO STUDENTS.

ST. BARTHOLOMEW'S HOSPITAL.

THIS ancient and popular hospital receives within its walls upwards of 6,000 in-patients annually, and its out-patients and casualties number more than 144,000 during the same period. Its staff is decidedly second to none. The clinical practice comprises a service of 710 beds, of which 322 are allotted to surgical cases, 227 to medical cases, 26 to diseases of the eye, 20 to diseases of women, and 81 to syphilitic diseases, while 34 are for convalescents at Highgate. Four house physicians and four house surgeons are appointed annually. The fee for these appointments is only nominal. The midwifery assistants, the ophthalmic house-surgeons, the clinical clerks, and the out-patient clerks and dressers are appointed, without fee, from among the diligent students. Sixteen free in-patient dresserships are awarded annually; other dresserships may be obtained on payment of the usual fees.

Accommodation is provided for residence of students in the college connected with the institution, for which an entrance fee of £2 2s. is required. By applying to the resident warden, Dr. Moore, students may obtain information respecting rooms in the college, or will be advised as to residence out of the hospital.

In addition to the many valuable prizes and scholarships open to students at this institution, new scholarships were founded in 1873 by the Brackenbury bequest of £2,000, and the Lawrence memorial gift of £1,000, enabling the Medical Committee to rearrange the distribution of the existing scholarships, and to found two scholarships in science—one an open scholarship, of the value of £100, to be competed for in September; the other, of the value of £50, to be competed for by students of the hospital of the first year in October.

Two classes are also held each year, for the convenience of gentlemen preparing for the matriculation examination at the University of London—from October to January and from March to June.

CHARING CROSS HOSPITAL.

This hospital, though at present one of the smaller ones, derives from its situation great advantages, It is in the very centre of London, where there is constant communication with every part. When the present extensive alterations are completed, which includes an additional floor over the entire building, about 250 beds will be at the disposal of the staff. In connection with it the practice of the Royal Westminster Ophthalmic Hospital, close by, containing 50 beds, is open to matriculated students, and affords an excellent opportunity for the study of that branch of the profession. There are also other special branches taught in the school, skin and mental diseases, and public health amongst the number.

The following scholarships are open to students:—Two entrance scholarships, of the value of £30 and £20 respectively tenable for one year, are awarded annually. Two scholarships are open for competition to matriculated students—the Llewelyn Scholarship of £25, for those who have just completed their second year; and the Golding Scholarship of £15, for those who have just completed their first year. The Governors' clinical gold medal, and silver and bronze medals in all classes are awarded annually.

There are clinical clerkships and dresserships, as at the other hospitals, and assistant surgical and medical officers to those further advanced in their hospital course. The fee for the three years' course of study is £78 5s., payable in five instalments. Dental surgery is taught on payment of a composition fee of 40 guineas. Students are also admitted without matriculation to the medical and surgical practice of the hospital for the full period required by the University of London, the Colleges of Physicians and Surgeons, on payment of a fee of 30 guineas.

ST. GEORGE'S HOSPITAL.

This hospital contains 353 beds, of which 205 are devoted to surgical, and 148 to medical cases. One great advantage to students is its unrivalled position, at the corner of Hyde Park, one of the most salubrious parts of the metropolis. Students can easily find lodgings within a few minutes walk. The school, both from the excellence of the staff and its general arrangements, offers every facility for education and preparation for the various examining boards.

In addition to the ordinary curriculum, separate courses of lectures are given on ophthalmic, aural, and dental surgery, and on psychological medicine, by lecturers who devote their attention to these branches of practice.

All the medical appointments, including those of house-physician, house surgeon, clinical clerks and dressers, are awarded to pupils, without additional fee, after examination.

The following paid offices are awarded yearly, upon the recommendation of the Medical School Committee—viz., Obstetric Assistant, with a salary of £100 and board and residence; Curator of the Museum, Medical Registrar, Surgical Registrar, and Demonstrator of Anatomy, with a salary of £50 each.

Students may become perpetual pupils by paying a compounding fee of one hundred guineas, and thus become entitled to admission to the practice of the physicians and surgeons, to the lectures, and to compete for all prizes and exhibitions.

Those who have commenced their professional studies at any of the English Universities will be admitted as perpetual pupils on payment of a reduced fee, calculated on the proportion of lectures from which they can claim exemption by producing certificates which will be accepted by the licensing bodies.

A compounding fee of 40 guineas each the first and second years, and 10 guineas each succeeding year, admits to the hospital practice and lectures required for the diplomas of the Colleges of Physicians, Surgeons, &c. Students in dental surgery are also admitted to the lectures and hospital practice required for the L.D.S. on payment of a fee of £45. Valuable prizes are given to successful students, and there is also a William Brown exhibition of £100 per annum, tenable for two years.

GUY'S HOSPITAL.

This old favourite borough school still attracts a lion's share of students. It has long been one of the most popular in the metropolis, and was the first to set the example of giving the appointments in its special departments to gentlemen not on the general staff.

Guy's is situated close to the London Bridge Railways. Hence great facilities for getting to any part of London or the country. It is quite practicable for students to reside a little distance down either of the lines that converge at this point, and thus enjoy the benefit of country air during their hospital career. For those who wish to live close to the hospital, lodgings are to be had at a moderate price, and there is plenty of room in the hospital grounds for out-door exercises and games.

The appointments are very numerous, and of the scholarships and prizes the following are the most noteworthy:—

Two gold medals are given annually to students who have not exceeded their fourth year for clinical medicine and clinical surgery, one medal being awarded in each subject.

Voluntary examinations are held at the end of the student's first summer session, for two scholarships of £50 and £25, and of £10 10s. Subjects: anatomy, physiology, materia medica, chemistry, and botany, or comparative anatomy. At the end of the second summer session, for two scholarships of £25 and £10. Subjects: anatomy and physiology. At end of the third summer session for two scholarships of £35 and £20. Subjects: medicine, surgery, midwifery, and medical jurisprudence. Moreover, with this year commences, on October 9th, an entrance examination with first and second prizes of £60 and £30, respectively. Subjects: classics, mathematics, modern languages, chemistry, botany, and physics.

Great facilities and encouragement are afforded for clinical study, there being special clinical wards, and clinical lectures are delivered every week during the whole sessional year.

The fees for hospital practice and lectures are—First year, £40; second, £40; third, £30; or on payment of 100 guineas a student is entitled to a perpetual ticket.

KING'S COLLEGE.

This College gives instruction in all the faculties, and has a theological department. It was established by members of the Church of England, in opposition to University College, which is a non-sectarian institution. The College is situated close to Somerset House, in the Strand, having a frontage on the new Thames embankment, within a few minutes' walk of several railway stations. A new wing has been opened recently, and a new dissecting room and laboratory, and new consulting rooms and offices erected. There is a junior school in connection with this college to prepare boys to enter the college at a proper age. The hospital is only a short distance from the college, at the back of the Royal College of Surgeons, and although smaller than some of the London hospitals, the renown of its staff has always kept up its reputation, so that King's is one of the most popular of the medical educational institutions in London. The physician's assistant, physician-accoucher's assistant, and house-surgeon, as also their assistants, clinical clerks, and dressers, are selected by examination from among the students, without extra fee.

The scholarships and prizes are very numerous at King's, and comprise—Warneford Scholarships.—Students entering the medical department of this college in October will have the exclusive privilege of contending for three scholarships of £25 each for three years. The subjects may be ascertained by applying to the secretary. Five medical scholarships are awarded at the close of each winter session for proficiency in professional subjects—viz., one of £40 for two years, one of £30 for one year, and three of £20 for one year. Sambrooke Registrarships.—Two of £50 tenable for two years. Daniell Scholarship.—One of £20 for two years, for proficiency in chemistry. Science Scholarship.—One annually of £25 for two years, given by the Clothworker's Company. Endowed prizes of the value of £25, £15, £10, and £4 4s. each, and college prizes of the value of £60 are annually awarded.

THE LONDON HOSPITAL.

The Medical College of the London Hospital has been greatly enlarged of late, and with its splendid hospital presents as fine a field for practical study, especially for surgery, as any in the metropolis. Lectures and demonstrations are given in all subjects required by the medical examining boards. The government of this college has been re-constituted, every department supervised, and a secretary appointed to ensure proper discipline, and promote the general improvement. Dr. Wilson, late demonstrator of anatomy at Cambridge, will superintend the teaching of practical anatomy, and Dr. John Millar of mental diseases. In the new building the museum has been more than doubled in size, and a physiological and histological laboratory has been erected and amply furnished with microscopes and all needful appliances. Pathology is also systematically and practically taught. There are now a large number of scholarships and prizes of considerable value, but more important still to studious men, all the numerous appointments in the wards are open to pupils without extra payment, and the value of the dresserships, clerkships, house-surgeoncies, house-physiciancies, and other residential positions in a hospital of the first magnitude are always considerably enhanced where the staff take such interest in the development of its educational resources as at the London. The new wing is now open, raising the number of beds to 800.

In addition to the scholarships which have been open to students in past years, two new ones are offered in natural science, of the value of £60 and £40 respectively, the examinations for which will be held on Sept. the 27th, 28th, and 29th. The subjects are the same as for the preliminary scientific examination of the University of London.

ST. MARY'S HOSPITAL AND MEDICAL SCHOOL.

This hospital is located, together with the medical school, at Paddington, in close proximity to the Great Western Railway Terminus. It has just been refitted and repaired, at a cost of £10,000, the system of drains and ventilation having been arranged on entirely new principles. Many of the pupils take advantage of the railway, and reside some few miles in the country, coming to town daily to attend the hospital practice and lectures. Students with slender purses will find the neighbourhood of the hospital a moderate one as regards lodgings, and easy of access by omnibus and the Underground Railway from all parts of London. This hospital was the first in which departments were made for the study and treatment of special diseases, and at the present time there are special departments for diseases of women and children, of the eye, the ear, the skin, and the throat, in which clinical demonstrations are constantly given by the physicians and surgeons in charge. Three resident medical officers are appointed for twelve months, and an obstetric officer for six months, who board free of expense in the hospital. A resident registrar is also appointed from among the students, with a salary of £100 a-year. These appointments are awarded after competition, without additional fee. In addition to the above, a demonstrator of anatomy is appointed annually, with a salary of £100 a-year, and the medical tutor in like manner, with a salary of £100 a-year. There are three scholarships in natural science, each tenable for three years, of the value of £60 the first year, £40 the second year, and £20 the third year; an exhibition in natural science of £20 for one year; a scholarship of £20 in anatomy, carrying with it the appointment of assistant demonstrator; a scholarship of £20 in pathology, carrying with it the appointment of assistant curator; and some extra prizes, particulars of which may be had of the Dean, Dr. Shepherd. Two of the above scholarships will be awarded by open competitive examination, in October, 1876; one in natural science, tenable for three years, of the value of £60 the first year, £25 the second, and £15 the third; the other in classics and mathematics, tenable for one year, and of the value of £35.

MIDDLESEX HOSPITAL.

The school attached to this hospital is not a large one, but its pupils have increased so unmistakably during the last few years that it is now a question of accommodation. The hospital now contains 300 beds, 180 being devoted to medical and 120 to surgical cases. There is a special department for cancer cases, affording accommodation for 33 in-patients, whose period of residence in the hospital is unlimited. Wards are also appropriated for the reception of cases of uterine disease, and of syphilis, and beds are set apart for patients suffering from diseases of the eye.

Special attention is bestowed on the clinical instruction of the students, both in the wards and out patients' rooms. Two Broderip scholarships, of the annual value of £30 and £20, tenable for two years, and two clinical prizes are annually awarded to those students who pass the most satisfactory examination at the bedside, and in the post-mortem room. Two entrance scholarships, of the annual value of £35 and £20 respectively, will be offered for competition at the commencement of the winter session. Each scholarship is tenable for two years, and are open to all who commence their studies in October next. Successful candidates will be required to become general students of the college. The examination will take place on September 28th and following days. The Murray medal and scholarship, in memory of the late Dr. John Murray, have been founded in connection with the University of Aberdeen, and will be awarded every third year to a student of this hospital. The governors' prize of twenty guineas, is awarded annually to the student who has most distinguished himself during his three years curriculum. Class prizes are also given, and six resident clinical appointments are annually awarded, after competitive examination, to students who have completed their education and complied with the regulations of the school. The officers thus appointed reside and board in the hospital free of expense. Clinical clerks and dressers are also appointed for six months, and are so arranged that every student may hold both a clerkship and a dressership at some period of his attendance on hospital practice.

The general fee for the curriculum required by the Royal College of Physicians and Surgeons and the Society of Apothecaries is £90, which may be paid by instalments. Fee for dental students, 40 guineas, which may also be paid by instalments.

ST. THOMAS'S HOSPITAL.

This magnificent building, or rather series of buildings, is situated at the foot of Westminster bridge, on the south bank of the Thames, facing the Houses of Parliament. From its proximity to some of the largest factories in London, it affords scope for surgical practice from accidents second to none, whilst amongst the members of its staff are names of European reputation in medicine and science.

There is accommodation for residence and free maintenance in the college-house for the resident assistant physician, resident assistant surgeon, two house-physitians, the resident accoucheur, two house-surgeons, one dresser, one obstetric clerk, and an assistant obstetric clerk, which appointments are awarded by competition. There are many prizes and scholarships.

The admission fee to practice and all the lectures is £40 for the first year, a similar sum for the second, £20 for the third, and £10 for each succeeding year, or £105 at one payment for unlimited attendance. Special entries may be made to any course of lectures or to the hospital practice, and a modified scale of fees is arranged for students entering in their second, third, or any subsequent year. Fee for general subjects required for students of dental surgery for two years, £45, or by instalments of £40 for the first year, and £10 for the second year. All students have the opportunity afforded them of being engaged in the performance of practical duties in connection with the medical, surgical, obstetrical, ophthalmic, and pathological departments in the hospital. There is the Tite Scholarship, value £30, for first year's students; the Musgrove Scholarship of 40 guineas, tenable for two years, for second year's students; and the College Scholarship of 40 guineas on alternate years, tenable for two years; the Mead medal for medicine; the Cheselden medal for surgery and anatomy; the Solly medal and prize; the Treasurer's gold medal; Grainger Testimonial prize; the entrance science scholarships of £60 and £40; three prizes for first year's students, at the end of both winter and summer sessions, of the aggregate value of £70, besides various medals and prizes open to students of any year.

UNIVERSITY COLLEGE AND HOSPITAL.

Few colleges in London have of late years been so successful as this, both in its annually increasing number of students and in the number of those who subsequetly pass their several colleges on first presentation. On its staff are names of considerable eminence, and from its central and healthy position everything is in its favour. The College, which is situated in Gower Street, about 100 yards from the hospital, gives instruction in every department of science, and specially prepares students for degrees in all the faculties at the University of London. As appears from the Fifth Report of the Royal Commission on Scientific Education, about one-third of the various degrees conferred by the University of London have been obtained by students from University College, although the University is open to candidates from every part of the British Empire, including the Universities of Oxford and Cambridge, besides a numerous body of colleges and other institutions in India, the various Colonies, and not a few Continental institutions. This fact, we think, speaks volumes, and is a source of just pride to the College authorities. There is a faculty of science. There is, however, no theological faculty in the College, which, like the University with which it is in intimate connection, is founded on the secular principle. University College School specially prepares boys to be ready at a proper age to enter the College. The scholarships and prizes open to students in the Medical Faculty are probably as valuable as those attached to any other medical school in the metropolis, Guy's and St. Bartholomew's excepted. There is the Surgical Fellowship, value £45 per annum for three years; the Physiological, value £70; Pathological Anatomy, £30; the Cluff Prize for Anatomy, Physiology and Chemistry; besides various other prizes and medals. There are also annually awarded three Entrance Exhibitions, of the respective values of £30, £20, and £10 per annum, tenable for two years, the subjects of examination being Classics, Mathematics, Natural Philosophy, and either French or German.

WESTMINSTER HOSPITAL.

The school attached to this Hospisal is the smallest in London. Its situation, however, is very convenient, near the Abbey and the Houses of Parliament. Lodgings are also very reasonable in the neighbourhood, and the school is one of the most moderate in respect to fees. The hospital contains 191 beds, and received during the past year more than 2,000 in-patients and 18,000 out-patients. There are separate departments for diseases of the eye, ear, skin, teeth, and diseases peculiar to women. In addition to the practice of the hospital, pupils who enter for the whole period of medical education are like those at the Charing Cross school, permitted to attend without further fee the practice of the Royal Westminster Ophthalmic Hospital, and that of the National Hospital for Paralysis. The whole course of study for the usual examinations may be here completed for £80, payable in two instalments. The perpetual fee is only 80 guineas, or £78 in one sum on entrance. Resident appointments, clerkships, and dresserships are all conferred without extra payments.

The scholarships are not so valuable as at some of the larger hospitals, but they are sufficient to induce students to employ their time to the best advantage, and are as follows: Exhibition in Anatomy and Physiology, value £10 10s., for first year's men. Prize of £2 2s., for diligence in the dissecting-room, for first year's men. A Scholarship in Anatomy and Physiology, value £21, tenable for one year, for second year's men. Prizes for histology, midwifery, clinical medicine and pathology, and for clinical surgery and pathology. The Frederic Bird Medal and Prize, for students who have completed their fourth year. Subjects: medicine, midwifery, diseases of women and children, and pathology; and the Chadwick Prize, £21, for general proficiency. There are also two Entrance Scholarships of £50 and £10 each, tenable for two years.

NOTE.—*Where fuller information is required by the reader than that contained in the foregoing notes, it will generally be found on reference to our advertising columns, where also will be found the names of the staffs, lecturers, &c.*

HOURS OF THE INTRODUCTORY LECTURES

To be delivered on Monday, October 2nd, at the different Metropolitan Schools.

St. Bartholomew's Hospital.—None.
Charing Cross Hospital—Dr. J. Mitchell Bruce.—4 p.m.
St. George's Hospital—Dr. Blandford.—4 p.m.
Guy's Hospital—None.
King's College—Prof. Baxter, M.D.—4 p.m.
London Hospital—Dr. Andrew Clark.—3 p.m.
St. Mary's Hospital—Dr. Wiltshire.—3.30 p.m.
Middlesex Hospital—Dr. G. H. Evans.—3 p.m.
St. Thomas's Hospital—Mr. Francis Mason.—4 p.m.
University College—Dr. Maudsley.—3 p.m.
Westminster Hospital—Dr. Allchin.—3 p.m.

◆

THE PRINCIPAL METROPOLITAN HOSPITALS TO WHICH NO MEDICAL SCHOOL IS ATTACHED

Open to Students from the larger Hospitals.

BETHLEM HOSPITAL.—This Hospital is open for the admission of two resident medical students, who have recently obtained their diplomas to practice Medicine and Surgery, for the acquisition of knowledge regarding the Insane. The next election takes place on the 9th of October, at Bridewell Hospital, and the elected candidates will be expected to commence residence on the 1st of November.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park.—This is a large and important hospital at the East End, containing 164 beds. Consulting Physicians: Drs. T. B. Peacock, J. Risdon Bennett, E. Lloyd Birkett. Consulting Surgeon: Mr. John Hilton, F.R.S. Physicians: Drs. S. H. Ward, J. Andrew, J. C. Thorowgood, Shepherd. Assistant-Physicians: Drs. Eustace Smith, J. B. Berkart, Evans, and Fothergill.

EAST LONDON HOSPITAL FOR CHILDREN.—Physicians: Drs. Barnes, Andrew Clark, J. M. Bruce, Eustace Smith, and Magrath. Surgeons: Messrs. B. Shillitoe, A. Cæsar, H. A. Reeves. House-Surgeon: Mr. J. Cæsar. Secretary: Mr. Ashton Warner.

FEVER HOSPITAL, Islington.—260 beds. Physicians: Drs. Twoedie, Murchison, Rroadbent, and Cayley. Consulting Surgeon: Mr. De Morgan. Resident Medical Officer: Mr. Mahomed.

GREAT NORTHERN HOSPITAL, Caledonian Road.—Physicians: Drs. Leared, Cholmeley, Cracknell, Cooke, Bridges. Obstetric Physician: Dr. Gustavus C. P. Murray. Consulting Surgeon: Mr. F. Le Gros Clark, F.R.S. Surgeons: Messrs. Gay, W. Adams, T. Carr Jackson, W. Spencer Watson, and W. H. Cripps. Ophthalmic Surgeon: Mr. Lowne. Aural Surgeon: Mr. Harvey. Dental Surgeon: Mr. C. J. Fox.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—This is the largest institution for the treatment of affections of the chest in the United Kingdom, and contains 257 beds. Consulting Physicians: Drs. C. J. B. Williams, W. H. Walshe, R. P. Cotton, and R. Quain. Consulting Surgeon: Sir Wm. Fergusson, Bart. Physicians: Drs. J. E. Pollock, E. S. Thompson, C. T. Williams, R. D. Powell, and J. Tatham. Assistant-Physicians: Drs. R. Thompson, Burney Yeo, F. Roberts, T. H. Green, and J. M. Bruce. Three clinical assistants reside in the hospital for a period of six months. Pupils are admitted to the practice of the hospital. Terms, £3 3s. for three months; perpetual, £5 5s.

HOSPITAL FOR DISEASES OF THE THROAT, Golden Square, W.—Clinical Instruction and Laryngoscopic Demonstrations are given daily on cases under treatment. Consulting Physicians: Dr. Billing, F.R.S. Consulting Surgeon: Sir W. Fergusson, Bart. Physicians: Drs. Morell Mackenzie, Semple, Prosser James, and Whistler. Surgeon: Mr. Pugin Thornton.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, Queen's Square, W.C.—This new building, recently opened by royalty, is probably the most magnificent children's hospital in Europe. The staff consists of—Physicians: Drs Dickinson, Gee, and Cheadle. Assistant-Physicians: Drs O. Sturges, A. L. Galabin, R. J. Lee, and Thos. Barlow. Surgeons: Messrs T. Smith, F. Howard Marsh, J. W. Haward, and Mr Owen. Surgeon-Dentist: Mr A. Cartwright. Fee for three months' attendance, £3 3s.; perpetual, £5 5s. Secretary: S. Whitford.

LONDON SCHOOL OF DENTAL SURGERY, Leicester Square.—This institution, which was removed a year since from its old and inconvenient quarters in Soho to its present much more commodious and attractive edifice, is the only recognised school of dental surgery in London. The meetings of the Odontological Society are also held here. In winter lectures are delivered on Mechanical Dentistry by Mr J. S. Turner, on Wednesdays, at 7 p.m.; on Metallurgy in Dentistry, by Mr. G. H. Makins, on Tuesdays and Fridays, at 6.30 p.m. In summer Mr S. H. Cartwright lectures on Dental Surgery and Pathology, and Mr C. S. Tomes on Dental Anatomy and Physiology. General fee for special lectures required for the curriculum, £15 15s. Fee for two years' practice at the Dental Hospital in connection with the above required by the curriculum, £15 15s.

ROYAL FREE HOSPITAL, Gray's Inn Road.—This hospital contains 102 beds. Of the smaller metropolitan hospitals few offer a more extensive field for students in medicine and surgery. Physicians: Drs O'Connor, Cockle, and Rickards. Surgeons: Messrs F. Gant and Rose. Secretary: Mr J. S. Blyth, from whom full particulars of the dresserships and clerkships may be obtained.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road, E.C.—This hospital, although it treats nearly 6,000 out-patients annually, is at present only able to receive 12 in-patients. A new wing, of which the foundation stone was laid by Princess Louise a few months since, will raise the number of beds to over 60. Consulting Physicians: Drs Herbert Davis and Horace Dobell. Physicians: Drs H. H. Crucknell, G. Goddard Rogers, P. J. Hensley, Gilbert Smith, and W. S. Greenfield. Consulting Surgeon: Mr J. Adams. Surgeon: Mr Walsham. House Physian: Dr Casby.

CENTRAL LONDON THROAT HOSPITAL, Gray's Inn Road.—The new building has been opened during the last few days, and in its incomplete state contains but 6 beds, but provision is made for 40. The staff consists of Mr. Carr Jackson, Consulting Surgeon, and Messrs. Lennox Browne and Llewelyn Thomas, Surgeons.

ROYAL LONDON OPHTHALMIC HOSPITAL, Bloomfield Street, Moorfields, is the largest of its class in the metropolis, and contains 70 beds. Consulting Physician: Dr F. J. Farre. Consulting Surgeon: Mr J. Dixon. Surgeons: Messrs Critchett, Bowman, Wordsworth, Streatfield, J. W. Hulke, G. Lawson, J. Hutchinson, J. Couper, and J. Soelberg Wells. Number of patients annually, about 20,000.

ROYAL ORTHOPÆDIC HOSPITAL, 315 Oxford Street, W.- Surgeon: Mr Brodhurst. House-Surgeon: Mr Baker.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Consulting Surgeon: Mr Henry Hancock. Surgeons: Messrs Henry Power, Jabez Hogg, James Rouse, and George Cowell. The hospital has, during the past few weeks, been closed for the addition of another storey, which, when completed, will place 14 extra beds at the disposal of the staff. Operations take place daily at 2 p.m., and the practice is open to officers of the public service. Students are admitted on the payment of a fee of £3 3s. for six months; perpetual £5 5s. Students of the hospital are eligible for the post of House-Surgeon.

SOUTH LONDON SCHOOL OF CHEMISTRY AND PHARMACY, 325 Kennington Road, S.E.—Director, Dr Muter. Lectures are delivered daily, at various hours, from nine till five, and the laboratory is open for practical chemistry from ten till four. Special instruction in Food Analysis is given daily at the Public Laboratory, Kennington Cross. The Winter Session commenced on Saturday last.

WEST LONDON HOSPITAL, Hammersmith Road, W.—A well appointed hospital, containing 68 beds. Consulting Physician: Dr Maudsley. Consulting Physician-Accoucheur: Dr W. O. Priestley. Consulting Surgeons: Messrs S. A. Lane and William Bird. Physicians: Drs Goddard Rogers and Thorowgood. Physician for Diseases of Women: Dr Wiltshire. Surgeons: Messrs W. F. Teevan and Alfred Cooper. Ophthalmic Surgeon: Mr B. J. Vernon. Junior Physicians: Drs Fish and Fothergill. Junior Surgeons: Messrs J. A. Bloxam and H. T. Butlin. Surgeon-Dentist: Mr H. E. Sewill. Analytical Chemist: Mr William Crookes, F.R.S. Resident Medical Officers: Two House-Surgeons and an Apothecary. Gentlemen desirous of acting as clinical clerks or dressers can obtain all information by application to Mr T. Alexander, at the hospital.

ENGLISH PROVINCIAL MEDICAL SCHOOLS.

BIRMINGHAM: QUEEN'S COLLEGE.

STUDENTS are admitted (1) as matriculated students who enter for their entire medical education; (2) as occasional students for one or more courses of lectures; (3) as junior students, to prepare for the preliminary examinations of the licensing boards.

Scholarships, Prizes, &c.—The Sands Cox Prize, value £20. Open to students who have completed their curriculum. Subjects: Medicine, Surgery, and Midwifery. Next examination in the third week in March, 1877. The Warden's Prize, value £5 5s., for first year's students, for general proficiency. The Percy Prize, value £5 5s., for German.

Fees.—College fees for all lectures amount to 50 guineas, payable by two equal instalments.

Hospital Practice is obtained at the General and Queen's Hospitals which have been amalgamated for the purpose of clinical instruction under the direction of the Birmingham Clinical Board, by whose order all schedules are signed and all examinations conducted. The hospitals have a total of upwards of 400 beds, and the staff attached is of a very high order.

All students will be required to attend six months alternately at each hospital, as directed by the Clinical Board, excepting students who enter the hospital for six months only.

Clinical Prizes.—The following prizes are given annually: —Senior Medical Prize, for third and fourth year's students, First Prize, £5 5s., Second Prize, £3 3s.; Senior Surgical Prize, for third and fourth year's students, First Prize, £5 5s., Second Prize, £3 3s.; Junior Medical Prize, for second year's students, First Prize, £3 3s., Second Prize, £2 2s.; Junior Surgical Prize, for second year's students, First Prize, £3 3s., Second Prize, £2 2s.; Midwifery Prize, £4 4s. The examinations for all the appointments and prizes are conducted by the Clinical Board, and are open for competition to all students registered by the Clinical Board.

Fees for attendance for four years on the medical and surgical practice, and on the clinical lectures at both hospitals, £31 10s. One year's attendance, £15 15s.; six months' attendance, £10 10s; Special Department, for Midwifery and Diseases of Women (optional), £2 2s. Dental fee (optional), £1 1s.

BRISTOL SCHOOL OF MEDICINE.—Attached to this school, where there is ample provision for education and practice, are two well-appointed hospitals, the Royal Infirmary, containing 242 beds, and the General Hospital, with 154 beds.

Competitive examinations are held amongst students of the first, second, and third years respectively, and prizes of money, instruments, and books are awarded annually.

The certificates of this school are accepted by all the examining boards.

The general perpetual fee is 55 guineas.

Medical and surgical hospital practice and clinical lectures are attended at the Royal Infirmary or at the General Hospital, at which institutions additional prizes and scholarships are annually offered for competition amongst the students. Arrangements are in progress for the establishment in Bristol of a College of Science and Literature, of which the existing medical school will form a department.

LEEDS SCHOOL OF MEDICINE.—Clinical Lectures are given by the physicians and surgeons attached to the General Infirmary. Ophthalmoscopic demonstrations and demonstrations of skin diseases are given in the Infirmary by the surgeons in each department, where also are obtainable six clinical clerkships and eight dresserships.

Besides the Infirmary, there is a large Dispensary and a Fever hospital, both of which are open to students of the School.

Students at this School have excellent opportunities of acquiring a thorough insight of psychological medicine, as the renowned West Riding Lunatic Asylum is in connection, and Dr. Major, successor to Dr. Crichton Browne, lectures on Mental Diseases. The systematic lectures are given at the School, and the clinical lectures at the Asylum, which now accommodates 1,500 patients.

Special prizes of the value of £10 each are given in the classes of clinical medicine, clinical surgery, and forensic medicine. Silver and bronze medals and books are given in the class examinations.

Composition fee, entitling to attendance upon all the required courses of school lectures, 44 guineas. The fees for attendance upon the medical and surgical practice of the hospital are 20 guineas each for three years, and proportionally less for single sessions. The fee for the comparative anatomy course is not included in the composition fee.

LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.—The Royal Infirmary attached to this School, which contains 300 beds with 40 special wards for the treatment of diseases of women, is perhaps second to none in England in its general appointments and the facilities it offers to students for gaining practical knowledge. Four exhibitions, value £31 10s. each, consisting of free board and residence in the Royal Infirmary for six months, with dresserships, on award of the Medical Board. Six dressers and six clinical clerks are elected quarterly. Two house-physicianships and three house-surgeonships are open to pupils of the School, who have obtained a legal qualification.

Fees.—For six months' medical practice, 5 guineas; twelve months', 6 guineas. Surgical, 6 guineas for six months; 8 guineas for twelve months (this includes admission to the practice of the Lock Hospital adjoining the Infirmary). Perpetual medical and surgical practice, 32 guineas. On payment of a composition fee of 45 guineas on entrance, or in two equal instalments (one-half on entrance, and the remainder within twelve months), the student is entitled to attendance on all the lectures and demonstrations (exclusive of practical chemistry) required for the membership of the Royal College of Surgeons, the licence of the College of Physicians and the Apothecaries' Society.

MANCHESTER—OWENS COLLEGE SCHOOL OF MEDICINE.—This School, as most of our readers are aware, has resulted from the amalgamation of the Manchester Royal Infirmary School of Medicine with the Owens College, and occupies in the provinces a somewhat similar position to that of University College and Hospital in London. It has a Faculty of Science as well as of Medicine, with departments of Laws and Arts. Since the amalgamation a new Medical School has been built, on the most approved principles, at the western extremity of the College estate. On the ground floor are two large lecture theatres, a library, and a museum. Over the lecture theatres is a dissecting-room, and over the library a physiological laboratory.

The course of instruction afforded to students is thoroughly complete. Three of the most important chairs, those of anatomy, physiology, and chemistry, are held by professors who entirely devote their time to the work of instruction.

Students wishing to engage in physiological or pathological researches will find opportunities for study in the complete and well-furnished physiological laboratory. Two valuable physiological scholarships are placed for competition in this branch as an incentive to original research.

Fees.—A composition fee, which may be paid in one sum of £48, or in two sums of £25 each at the commencement of the first and second years of studentship, admits to the whole of the lectures required to qualify for the examinations for medical degrees in the University of London, the diplomas of the Royal College of Physicians, the fellowship and membership of the Royal College of Surgeons, and the licence of the Apothecaries' Society, and to attendance on the class of practical anatomy during two winter sessions. In addition to the composition fee, all students (except those who entered before the 1st May, 1873) will be required to pay the Medical Tutor's Fee, £2 2s. annually. Should a student desire to continue his study of practical anatomy beyond two sessions he can do so on payment of extra fees at the rate of £2 2s. for a three months', or £3 3s. for a six months' course.

An extra fee of £1 1s. will be charged for attendance on the demonstrations in the comparative anatomy class, and a like extra fee for the demonstrations in botany. A charge of £1 1s. is also made for the chemicals used in the class of practical chemistry.

NEWCASTLE-ON-TYNE COLLEGE OF MEDICINE.—This school is a department of the University of Durham, and contains ample provision for acquiring a sound education and practical experience at the bedside. It is smaller than some of the provincial schools, but with some parents and students this would be considered an advantage.

Hospital practice is obtained at the Newcastle Infirmary, which has 230 beds, and in which the required clinical lectures are delivered.

Scholarships and Medals.—Four Scholarships of £25 a year each, tenable each for four years. Dickenson Memorial Scholarship, £15, tenable for one year, for general proficiency. Tulloch Scholarship, £20, tenable for one year, for Anatomy, Physiology, and Chemistry. Charlton Memorial Scholarship, £35, tenable for one year, for Medicine. Four resident dressers, who also act as physician's clinical clerks, are chosen every six months from the senior students. Two assistants in the Pathological Departmene are chosen every six months.

Fee for hospital practice and clinical lectures, twelve months, £7 7s.; six months, £5 5s. Composition fee, £17 17s., or if paid by instalments, first year, £7 7s.; second year, £6 6s.; third year, £5 5s. Composition fee to all the lectures, 50 guineas.

Sheffield School of Medicine.—Students at this College obtain excellent instructions in medical and surgical practice at the General Infirmary, which contains 200 beds, and is provided with a museum and pathological and post-mortem theatres.

The fees for perpetual attendance are £15 15s. for medical, and £21 for surgical practice; for 12 months' medical and surgical practice, each £10 10s.; and for 6 months', £6 6s. each. There is also the Sheffield Hospital and Dispensary, containing 104 beds, and is recognised by the College of Surgeons and the Hospital for Diseases of Women, to which students are admitted.

The perpetual fee, for attendance on all the lectures required by the Royal College of Surgeons and the Apothecaries' Hall, £42. Prizes to the value of £30, and certificates of honour, are given annually.

Some of the lecturers, and other local members of the profession, receive house pupils, which will be found far preferable to life in ordinary lodgings.

Liverpool Royal Southern Hospital.—This Institution is one of the largest in the English provinces, and contains 200 beds. It has no school proper, although it contains accommodation for resident pupils, and clinical lectures are delivered daily by members of the staff. These, together with the practice obtained here, which is of a very varied and valuable character, is recognised by all the Examining Boards. Inclusive fees—perpetual, 25 guineas; one year, 10 guineas; six months, 7 guineas; three months, 4 guineas. Students can enter to the medical or surgical practice separately on payment of half the above fees.

Note.—*Our advertising columns, of which an Index will be found at end, will supply further information, with the names of staffs, &c., attached to the foregoing schools.*

HOURS OF THE INTRODUCTORY LECTURES

To be delivered on Monday, October 2nd, at the different Provincial Schools.

Durham University—2 p.m.
Queen's College, Birmingham—Mr. J. V. Solomon—3 p.m.
Leeds School of Medicine—Dr. R. T. Land—4 p.m.
Liverpool School of Medicine—3 p.m.
Manchester, Owen's College—Dr. J. E. Morgan—3 p.m.
Sheffield School of Medicine—Dr. W. R. Thomas—4 p.m.

◆

MEDICAL EDUCATION IN IRELAND.

THE CAREER OF THE IRISH STUDENT.

The practice of the profession in Ireland, though not nearly as remunerative as in England, still affords a certain prospect to any medical man who is content with modest independence. Irish medical men pride themselves on holding a higher social position than the English general medical practitioner. They are entitled to meet the gentlemen of their locality on terms of equality, and it is not necessary or usual for them to endanger their prestige by the adoption of the trading or Christmas bill system which obtains elsewhere. In fact, what they lose in income they gain in rank.

In order to put the career of the Irish student as plainly as possible, we narrate his progress, from the day on which he takes his first step towards medicine to the hour of his issue from the cocoon of his studentship a fully-developed surgeon.

His parents and guardians have, after much discussion, decided that he shall be a doctor. He has had a moderate amount of schooling, at least the very moderate amount which is essential for the medical preliminary examination, and his father is ready to expend about £130 on his medical education, that sum being divided over four years, or paid down in order to secure the advantage of a considerable saving.

THE CHOICE OF UNIVERSITIES AND COLLEGES

Will depend on various circumstances, and on the aspirations of the student. If he is intended to make a fortune and enlighten his generation as a metropolitan practitioner, and if money and education are plenty he will probably take University degrees in arts and in his profession. If the attainment of good professional rank on moderate terms be desired, the College of Surgeons and College of Physicians will serve every purpose. For any University degrees which are of any value, it is to be remembered the student must undertake the prolonged study of classics and science in addition to his medical, surgical, and anatomical studies; and he will have to pay a considerable sum for this course of teaching. But if he is content to face the expense and labour, he will enter the profession with all the prestige of an educated gentleman. In fact, the question whether he will, or will not lay out for himself a University graduation in arts and medicine, depends principally on whether he has money and time to give to it, and whether or not he means to practise in the metropolis. The Queen's University places at the disposal of the student a cheap University degree, and thereby attracts many applicants, who are at liberty to write M.D. after their names, and are only called upon for a low curriculum, and a nominal residence in the Queen's College.

The College of Surgeons and Physicians of Ireland confer qualifications which may stand well beside any in the United Kingdom, and as they do not require either residence or anything more than a single arts examination, they continue to be the licensing bodies for the rank and file of the profession in Ireland. If a student contemplates provincial practice—the army or navy—or a dispensary, he will most probably take the usual licences from the two Colleges. If he contemplates the lowly function of a country apothecary, he may take the licence of the Dublin Apothecaries' Hall, which is *in law* equivalent to a medical degree; or the license of the Irish Pharmaceutical Society, which will licence all those who desire to practise pharmacy. If he hopes to achieve a considerable private practice, he will find it necessary to obtain other medical and surgical degrees.

THE CHOICE OF SCHOOLS.

It must not be supposed that a student who intends taking a degree or diploma in any college need take his lectures in the school attached to that college, if there be one. On the contrary, with few exceptions, all certificates of attendance on lectures are interchangeable, and a student, no matter what medical school he may have studied in, will be admitted to any university or college. To this rule there is an exception. The Queen's University insists on certain courses being attended in one of the Queen's Colleges, by which means it enforces a brief residence in the Colleges.

There is in some cases a sort of semi-official connection between certain colleges and hospitals,—as between Trinity College and Sir Patrick Dun's, between the College of Surgeons and City of Dublin Hospital, and between the Catholic

University and Mater Misericordiæ Hospital; but this connection only exists because the professors of the college are in many instances officers of the hospital, and it confers no special immunity or privilege on the student of such hospital.

The choice of a school, hospital, or college having been made, the tyro is perhaps sent to these to pass his

PRELIMINARY EXAMINATION

in general education, but if he is either lazy or ignorant, he may adjourn that unpleasant process, *de die in diem*, until the eve of his final qualification as a surgeon, when, if he does so, he will find himself in possession of a mental muddle of Latin and physic. The preliminary examination is, however, not to be feared.

We strenuously advise the parents of the student to insist on his passing his preliminary education before he enters a medical school or hospital, and thus the student will relieve his mind of the apprehension of a future examination, which he will assuredly put off to the last moment if he can. In England the four years of medical study required to pass do not commence to count until the preliminary is passed. It should be so in Ireland, but is not.

The preliminary examination (of the subject of which details will be found in the official regulations of each college) having been passed or postponed, he comes to town to begin work.

He may do so either (1) on his own account, or (2) he may become voluntarily a pupil of some medical man, usually a teacher or hospital surgeon, who can assist him in his studential course. This is by no means a requirement of any of the colleges; it is purely a matter of option. Should the student pursue the first course he usually comes to town, takes a lodging close to his school and hospital, either by himself or in companionship with some *chum*, and either arranges to maintain himself or to board with his landlady. There is, of course, every degree of expense and comfort, but we should say that reasonable yet frugal living may be had in Dublin at about 10s. per week for lodging, and £5 to £6 per month for maintenance. He may also reside with a medical man, without entering upon any apprenticeship with or receiving any instruction from him. For his board and residence in such case the payment is from £7 7s. to £8 8s. a month.

COST OF EDUCATION.
